Clinical Lectures
ON
CASES OF DIFFICULT DIAGNOSIS.

By SAMUEL FENWICK, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE II.

STRICTURE OF THE ILEO-CÆCAL VALVE.

GENTLEMEN,—At our last meeting we were considering the subject of perforation of the vermiform appendage; and we found that by a careful consideration of its symptoms, and the physical signs accompanying it, the existence of the complaint could be generally diagnosed. I now wish to draw your attention to another disease of the cæcum that is very difficult of recognition. The cases are often so obscure that I have not ventured upon an exact diagnosis in any of those that have come under my own notice, but have had to content myself with the opinion that there was a stricture in some part of the intestinal canal. It will, however, be evident that, unless we can satisfy ourselves as to the position as well as the nature of the disease in a case of this kind, the treatment must be vague and uncertain. I will first read to you the cases to which I have referred, and you will see at once how greatly they differ from each other in their history, in their clinical aspects, and in the cause of the obstruction discovered after death.

CASE 1. Sarah J——, aged twenty-nine, admitted into the London Hospital on November 6th, 1874. She complains of a fixed pain near the umbilicus, coming on directly after food. She has no vomiting and no heartburn, but suffers from slight acidity and excessive flatulence. Tongue rather dry, thirst, bowels much confined, and only act with the assistance of aperients; pulse 84. She has latterly lost flesh. Catamenia have not appeared for seven weeks. The abdomen is greatly distended and is divided into longitudinal ridges, which are continually altering their position, their motions being very apparent. There is no tenderness on pressure. The uterus is normal, and no cause for intestinal obstruction can be discovered by vaginal examination. The percussion note is very tympanitic in every part, but the left side is more prominent and more clearly tympanitic than the right. After drinking no gurgle can be detected in the stomach by succussatory percussion. She states that she had always enjoyed good health until three months ago, when she was suddenly attacked with severe pain near the umbilicus, accompanied by diarrhœa. This attack lasted eight days, and ever since that time she has suffered from attacks of pain of the abdomen, which are increased by exercise as well as by food, and from occasional vomiting, which chiefly comes on in the evenings.—Dec. 24th: The vomiting has ceased since her admission, but she still complains of pain at the umbilicus, coming on a short time after food. The bowels now act regularly with the aid of enemata. The movements of the intestines have become more visible and are very well marked.—January 8th, 1875: The pains are now much more severe than formerly, and the whole of the front of the abdomen seems to be occupied by a mass of moving intestinal coils. She had vomited a large quantity of pure bilious fluid mixed with mucus. Pulse 120, small and feeble. She died rather suddenly, without any alteration either in her symptoms or the physical signs.

Post-mortem examination.—The small intestines were found to be enormously distended, especially the ileum; this contained a dark-coloured fluid; their walls were much thickened and numerous hæmorrhages were found in the mucous coat; the ileo-cæcal valve was much contracted, and numerous small openings existed in its place between the small and larger intestines; some solid fæces were in the ascending colon; the descending colon was much contracted. The other organs of the body were in a healthy state.

CASE 2. Fanny F——, aged twenty-seven, admitted August 29th, 1877. She complains of severe pain of the abdomen, coming on in paroxysms, attended with occasional vomiting; the pulse is 100, the tongue furred; appetite bad; temperature 100°; the bowels have been confined for two weeks. The abdomen is much distended and tympanitic; no dulness can be discovered in any part, but there is increased tension and resistance to pressure in the right iliac region, although no tumour can be felt there. The motions of the intestines are visible over the whole abdomen; they are constantly present, but seem to be most distinct in the umbilical region. Catamenia irregular. On examination by the rectum, a round, hard mass can be felt, apparently in Douglas's pouch, and the uterus seems to project forward. She gives a very confused account of her illness; but as far as can be learned from her, she had four years ago suffered from what she calls a "miscarriage," and the child came away in pieces, during a period of five months. After this she suffered for two years from severe pains of the abdomen, which came on at intervals. These paroxysms of pain then left her, but two months ago she was again attacked with severe pain in the bowels, accompanied by a hard swelling and a feeling of movement in the abdomen, and with vomiting. After her admission the bowels were freely opened by enemata, and a large quantity of brown-coloured fæcal matter was evacuated.—28th: The liver dulness extended from the upper border of the fourth rib to the upper border of the seventh, and some dulness was found in the right flank. The patient was examined under chloroform, and a small, rounded, hard swelling was discovered in the recto-uterine pouch. A copious enema was thrown up above the tumour, but it was not retained. The temperature rose to 102°, but no pain was complained of.—29th: The patient seemed to be somewhat relieved, but she suddenly became collapsed when straining at stool, and vomited some fæcal-looking fluid. She died the same evening.

Post-mortem examination.—Many of the coils of the intestines were adherent, and a communication existed between the cæcum and a portion of the small intestine adherent to it, whilst the sigmoid flexure was adherent to the rectum, and a communication also existed between them. The lower end of the ileum was much dilated and hypertrophied, and the ileo-cæcal valve was contracted to the size of a swan's quill. There was a cyst connected with the left Fallopian tube, and a fœtal parietal bone is also mentioned in the notes; but its exact situation is very difficult to make out, as in one account it is stated to have been situated in the sigmoid flexure, in the other in the cyst.

CASE 3.—James G——, aged forty, admitted June 6th, 1883, complaining of pain in the abdomen of a paroxysmal character, coming on every three or four minutes, and attended with vomiting of all food. The pain is so severe that it prevents him from sleeping, and he cannot lie in any position very long. The bowels have not been moved for nine days. Pulse 92; temperature 99·6°. The abdomen is slightly tense and painful on pressure, and the movements of the intestines are very visible; no tumour can be felt, but there seems to be more fulness to the left than to the right of the spine, and the percussion note is rather duller there. The rectum is large, and no stricture can be discovered. Large enemata were employed, but no stool was obtained. He had resided in Assam for seven years, and had visited various parts in India, but had generally enjoyed good health. He contracted syphilis twenty years ago, had malarial fever and ague some years ago, and had suffered from slight attacks occasionally since then. He first felt griping pains in the abdomen about one month since, and took aperient medicines, which produced purging, but did not relieve the pain. During the last month he has taken purgatives about half a dozen times, the last three times with little or no effect. On the last occasion (June 5th) it produced pain and uneasiness with nausea, and about seven or eight hours afterwards he vomited, and continued to do so at short intervals for many hours. He has at present a sore on the leg, apparently syphilitic, which has been unhealed for the last four years. 11th: He was carefully examined under chloroform, but no stricture could be discovered. He describes the pain as commencing at the level of the umbilicus, and then passing down each side, each access of pain being attended with great rumbling of wind.—13th: He has had two slight stools to-day; the first was liquid, the second solid, but of small size; the abdomen is not so tense, and is not tender on pressure.—15th: He seems easier, the pain coming on at intervals of about one hour, but relieved by change in his position. The abdomen is less distended, and there is dulness over the cæcum and ascending colon. The movements of the intestinal coils are

very apparent. He varied from this date, the pain and vomiting being one day easier, another day more severe. The operation of colotomy was first performed, but the colon being found contracted the small intestine was opened, with the result of giving vent to a large quantity of liquid fæces. He was greatly relieved, but some colicky pains still continued, and he was attacked with pneumonia on July 1st, of which he died on July 6th.

Post-mortem examination. There were some old peritoneal adhesions in the pelvis; the ileo-cæcal valve was much contracted, and only admitted the point of the forefinger; there was some thickening of the ileum near the valve with a semilunar ulceration, and a little further along the ileum was a raised patch with ulceration. The other organs were healthy.

The three cases I have just quoted are the only instances of this disease that have fallen under my own notice, or at any rate they are the only ones in which stricture of the ileo-cæcal valve was proved to be present by post-mortem examination. I have only been able to discover one other in the post-mortem records of the hospital, and no history of the case can be found. The account merely states that a sailor, forty-five years of age, died in July, 1851, and the ileo-cæcal valve was obstructed by a scirrhous growth completely surrounding the intestine and leaving an aperture through which only a crowquill could be passed. The large intestine was contracted; the small intestines were distended with fluid and flatus, they were of a dark-slate-colour and much congested, and the muscular coat was thickened. Cases of cancer of the cæcum are recorded, but as there is no mention of stricture of the valve these cannot be taken into the account. In an admirable paper on Intestinal Obstruction by Dr. Hilton Fagge twenty-two cases of intestinal obstruction are quoted as having occurred at Guy's Hospital from January, 1854, to November, 1868, and only one is mentioned in which the cæcum and ileum were the seats of stricture, the former intestine "being puckered by scar-like patches of cancer on the peritoneal coat," but no mention is made of any stricture of the valve. M. Duchaussoy collected twenty-seven cases of stricture of the intestines, in only one of which the cæcum was the seat of disease, but no mention is made of the state of the ileo-cæcal valve. I have, however, been able to collect twenty-six cases of stricture of this valve, recorded by various authors; and although in many the details both of the morbid conditions and of the symptoms during life are very meagre, they will, I hope, furnish materials that may assist us in our study of this rare form of disease.

You will remark that, although the cases I have quoted all showed a contraction of the ileo-cæcal value, there was a considerable difference in the morbid conditions associated with it. Let us look, for instance, at Case 1; in it, although the valve is described as obstructed, there is no mention of any disease of the intestines or of the adjoining structures, and it is stated that a number of small openings in the site of the valve existed between the ileum and the cæcum. In the catalogue of the Dupuytren Museum, in Paris, a similar case is described, in which at the contracted part there were a number of bridles crossing the opening, and thus affording the appearance of a sieve. It is suggested by the writer of the catalogue that the stricture had originated in an intussusceptum, and that the bridles were the remains of small portions of the included intestine that had escaped the sloughing process. This was, in all probability, also the origin of the contraction present in Case 1; for you will remember that the patient referred the commencement of her complaint to an illness which lasted for eight days, and had commenced suddenly with severe pain near the umbilicus, accompanied by diarrhœa. The objection will probably occur to you that females who were the subjects of both of these cases are more rarely affected by this form of invagination than the other sex; but if you bear in mind the sudden nature of the attack, occurring in a person who had been always previously in good health, the length of the primary illness, the gradual development of the symptoms after it, and the peculiarity of the morbid appearances found after death, you can have but little doubt that this explanation of the case is correct.

When we last met we were considering the abscesses near the cæcum produced by ulceration of the vermiform appendix, and you might reasonably suppose that a contraction of the ileo-cæcal valve would often result from such a condition. This is, however, not the case, for I have only been able to find one example of the kind, which is recorded by Dr. Hensinger. The patient had eleven years before her death suffered from an attack of perityphlitis; and on post-mortem examination the ileo-cæcal valve was found to be completely closed, the communication between the small intestine and the cæcum being maintained by three fistulæ, which passed from one to the other through thickened tissue, the remains of an old abscess around the cæcum. The rarity of this termination of perityphlitis may be explained by the fact that most of such cases end fatally within a short period, and that when life is prolonged for many weeks the abscess is discharged, either through some of the neighbouring organs or by the pus making its way to the surface of the body.

In eight cases out of twenty-six the ileo-cæcal valve is stated to have been contracted, and in six it is recorded as contracted and indurated, without any mention being made of a malignant growth accompanying it; so that in more than half of the whole number the morbid change seems to have been due to chronic inflammation alone. In one instance, recorded by Dr. Wickham Legg, the contraction was believed to have been congenital, for the patient had suffered from severe attacks of colic since the age of five, and a large number of cherry-stones were discovered above the stricture. It was suggested by Schroeder van der Kolk, in a case that came under his observation, that the stricture might have originated from ulceration produced by the impaction of a foreign body; but this must be a very rare cause, as I have been unable to find any history of a previous intestinal obstruction, either in the cases that have occurred in this hospital or in those recorded by other observers. But it has been frequently remarked that the cæcum was also thickened, and when we remember how frequently this portion of the intestinal tube suffers from inflammation, we should feel surprise that the valve is not more commonly the seat of stricture. It is not uncommon to find tubercular and typhoid ulcerations on the mucous membrane of the ileo-cæcal valve, and it is strange that such lesions do not more frequently lead to permanent narrowings; but I am strongly inclined to suspect that a moderate amount of stricture is more common than is supposed, and that it is often overlooked on account of the absence of symptoms during the life of the patient.

Let us now turn our attention to the third case, where there was thickening and ulceration of the mucous membrane at the lower part of the ileum, in addition to the stricture of the valve. This man had suffered from syphilis, and had an ulcer of the leg, apparently syphilitic, at the time of his admission. A very similar case is recorded by Dr. Bartels, in whom, although the patient denied ever having had syphilis, there was found after death contraction of the ileo-cæcal valve and extensive ulcerations of the cæcum and small intestines, and also indurations in the lungs, which were considered as decidedly syphilitic. Now, these cases are of great interest, not merely as showing that ileo-cæcal stricture may be the result of inflammation of the neighbouring intestines, but also as pointing to syphilis as the probable cause of the local mischief. The very striking cachexia so often accompanying syphilis is scarcely to be explained by the lesions we are accustomed to find after death; but, if it could be proved that the secreting and absorbing surfaces of the gastro-intestinal tract are as often the seat of mischief as the skin and mucous membrane of the mouth, we should make a considerable advance in our knowledge of the effects produced by this malady. That this must often occur I am fully convinced, for I have seen most obstinate cases of gastric ulceration and of dyspepsia following syphilis which have quickly yielded to the use of iodide of potash and other remedies of a similar character. In order, however, to discover the presence of such changes, after death it would be necessary to employ careful microscopical investigation, for important alterations are often present in the mucous membranes without producing any alterations that can be recognised by the naked eye. In nine out of twenty-six cases the stricture is stated to have been produced by cancer, and in two of these the cæcum was also affected. I would here draw your attention to the extreme rarity with which primary carcinoma affects the cæcum, as compared with the frequency of its presence in the stomach, colon, and rectum; for any theory that may be brought forward to account for the origin of this malady must take into consideration its predilection for certain parts of the gastro-intestinal tube as compared with others.

As might be supposed, inasmuch as strictures of the

ileo-cæcal valve are produced by different agencies, the amount of obstruction greatly varies. Thus in five cases the little finger could be barely passed through the valve; in one this could not be effected; in another the opening was only one quarter of an inch in diameter; in five it only admitted a quill, and in one a needle; in one it was almost completely closed, and in four no opening at all could be observed. Of course the effects of the constriction also vary, for wherever it was very narrow the small intestines were found to be vastly distended with fluid, the muscular coat of the ileum was hypertrophied, and the results of vascular congestion were seen either in recent extravasations of blood or in the slate colour of the walls of the gut; the colon was nearly contracted, although in many cases it contained a small amount of fæces. In Case 2 adhesions were found between a coil of the small intestine and the cæcum and between the sigmoid flexure and the rectum, and communications had been established between these portions of the intestinal canal, so that the effects of the distension must have been considerably lessened. I have found three other cases on record in which a similar process had taken place; in one a communication had been established through the appendix vermiformis, which was much dilated, and was adherent to the ileum; in the others intestinal fistulæ had been established between the small and large intestines. Old adhesions have been often met with, and are probably the results, as in Cases 2 and 3, of a previous attack of local peritonitis, or of inflammation excited by the great distension to which the gut had been subjected.

(To be concluded.)

Remarks
ON
LARYNGEAL PARALYSIS AND INEQUALITY OF THE PUPILS, AS TENDING TO AID AND ALSO TO MISLEAD IN THE DIAGNOSIS OF THORACIC ANEURYSM;
WITH SOME OBSERVATIONS ON THE
STATE OF THE PUPIL AFTER DEATH AND THE EFFECT OF ATROPINE.

By JAMES FINLAYSON, M.D.,
PHYSICIAN AND LECTURER ON CLINICAL MEDICINE, GLASGOW WESTERN INFIRMARY, PHYSICIAN TO THE GLASGOW HOSPITAL FOR SICK CHILDREN, ETC.

THE occurrence of laryngeal symptoms, and particularly of laryngeal paralysis, as also the appearance of inequality of the pupils, have been known for many years as affording important evidence of the presence of aneurysmal and other thoracic tumours. Two patients who were in my wards at the same time afforded illustrations of the value of these signs, and also of the danger of trusting too much their significance.

In the one case we had a well-marked pulsating tumour in the upper part of the chest, extending into the right side of the neck. The history of the case went back for more than a year. The examination after death showed that the aorta was dilated and that a large aneurysm arose from the arch in front of the origin of the great vessels. The pneumogastric and recurrent nerves on the right side were found considerably stretched over the tumour, and somewhat adherent to it as well. An attempt was made to include the sympathetic in the dissection of the parts removed; but although it was distant from the position of the tumour that it must have been implicated, it was found that it had been partially destroyed in removing the aneurysm and its connexions. The laryngeal symptoms had appeared three months before death, and on admission the right vocal cord was found to be paralysed. During his stay in the ward (six or seven weeks) the dyspnœa was often extreme, and he had had several attacks, almost fatal in character, due to spasm of the glottis, terminating with a crowing inspiration. These attacks were aggravated by the growth of the tumour leading, a few days before death, to displacement of the larynx and trachea to the left of the middle line. The only point in this part of the history worthy of note is that the tumour and paralysis were on the right side. It would seem from the statements of authors that this symptom is much commoner when the tumour is on the left side. The state of the pupils was noted particularly on admission; they were quite equal. Their size was measured by means of the scale enclosed in Nettleship's pocket case, the round black spots in which are numbered so as to express the diameter in millimetres. Both pupils when shaded were 7½ mm.; when exposed to bright light, 4½ mm. On being measured again, three weeks before death, when a marked inequality had appeared, the figures were: right pupil when shaded, 4½ mm.; when exposed to light, 4 mm.; left pupil when shaded, 6½ mm.; when exposed to light, 5 mm. This inequality persisted to the end of the case, and was frequently verified as essentially the same in degree. The exact condition at the moment of death was not noted, but at the post-mortem examination, thirty-six hours later, I found both pupils dilated and quite equal. This dilated and equal condition of the pupils after death, where myosis dependent upon aneurysm was present during life, was noticed in the earliest cases recorded of this symptom.[1] This condition of the pupils after death in cases of paralysis from aneurysm is just what might be anticipated; for such tumours do not usually destroy the nerves implicated, and so when relief to the aneurysmal pressure occurs at the time of death the paralytic condition might pass away at the end; and, further, after death the sphincter of the pupil, like other muscles, becomes no doubt relaxed; and so the condition of the pupil should not be different from what is observed in other cases immediately after death occurs. Some observations have been made in my wards on this point, for which I am indebted to the sister of my wards, on whose care in such a matter full reliance can be placed; and although not sufficiently numerous to warrant an authoritative statement on the subject, I may say that if observed *immediately* after death, the pupils were usually found moderately dilated, or sometimes even very markedly so, from 6½ mm. to 8½ mm. being common; none were noted under 5 mm., and once even 10 mm. was found. No doubt the influence of age, the nature of the illness, and other conditions affect the state of the pupils at the time of death. But on pursuing the inquiry after the removal of the body to the dead-house, my assistant, Dr. Williams, and I found that the pupils often changed their size shortly after death, and speaking only from a few cases, I believe there is a marked tendency towards contraction, so that in a young child the reduction found was from 7½ mm. to 4 mm. within sixteen hours, some distinct diminution in size being found in various other cases. In the case of a person recently dead, the influence of atropine in causing very marked dilatation of the pupil is readily shown[2] by putting a few drops of a strong solution of atropine into one eye and none into the other, when a comparison can be made in an hour or two. Sometimes the effect of the atropine appears just to be sufficient to neutralise the tendency to contraction as manifested in the diminution of the other pupil. Even when put in immediately after death, we did not see the *extreme* dilatation so often produced by strong applications during life. If some hours be allowed to elapse after death before atropine is added, the effect is less pronounced; and it seemed as if after four or six[3] hours the susceptibility to atropine was almost lost. The atropine, however, may continue to act even after well-marked rigor mortis has been established. This was a point to which I directed attention, as it seemed to me that the progressive contraction of the pupil after death was concurrent with, and might be dependent on, the development of rigor mortis. Even, however, when the action of the atropine is well marked on the dead eye, its influence is short-lived. This may account for its not producing the extreme dilatation so often seen during life. Within a few hours of its production, say

[1] Dr. W. T. Gairdner, Clinical Medicine, Edin., 1862, p. 534. The case was observed in 1855. See also a case observed by Dr. Walshe in 1853, mentioned in a footnote to his Diseases of the Heart, 4th edition, London, 1873, p. 496.

[2] Curiously enough, the effect of the instillation of atropine has actually been proposed as a test of death (!), but the dilatation of the pupil in dead eyes, and even in those which have been removed, seems to be well known. See Dr. Argyll Robertson's interesting paper in the Edin. Med. Journal, Feb. 1869, vol. xiv., p. 703.

[3] This I find is the average time named by Maschka, within which marked post-mortem changes can be recognised in the eye. Handbuch der gerichtlichen Medicin, Band III., S. 308. Tübingen, 1881-82.

twenty-four hours after death, we usually found the dilated pupil had become reduced to the size of the other; this of course presents a strong contrast to the persistence of the dilatation of the pupil for some days with which we are familiar during life. These facts are of course open to various interpretations, but they seem to me, particularly the one last mentioned, to lend some support to the theory of the dilatation of the pupil from atropine being due not only to its paralysing the sphincter, but also to a direct stimulation of the dilator of the pupil.[1]

In leaving this interesting subject, I may say that I am aware that my observations are too few to warrant a conclusive statement of the case, and as my opportunities for following up such an inquiry are not likely to enable me to do so myself I have requested one of my former assistants to study the behaviour of the pupil after death, and he has already made some progress in the inquiry.

In the second case, where the signs of laryngeal paralysis and inequality of the pupils helped to mislead us, there were very obvious signs and symptoms of cardiac disease, great dyspnœa, enlargement of the heart, and a double murmur, audible down the sternum. But there was also evidence of dilated aorta, as shown by an area of undue dulness on percussion extending from the upper boundary of the heart towards the right sterno-clavicular articulation, and also by an undue pulsation in the jugular fossa. Moreover, we had at times a very distinct sense of impulse immediately under the left clavicle. There was also substernal pain, and this extended down the left arm, but there was no swelling. The pulses were throughout quite equal, and the tracings had a well-marked aortic regurgitant character. Frequently, also, we had, from the time of admission, a slight inequality of the pupils; this was not persistent, but when present the left pupil was always the larger of the two. These facts led me to suspect, almost from the first, the presence of an aneurysm occupying chiefly the descending part of the arch of the aorta, acting on the sympathetic by causing irritation and so leading to dilatation of the left pupil. The patient, a man of forty-two years, had an old history of rheumatism, but not of syphilis. The total duration of his illness from first to last was fully two years; he was in the wards on three separate occasions, and the observation of the case extended over a period of thirteen months, during the whole of which time the suspicion of aneurysm was entertained. The symptoms varied in degree, but remained much the same in kind. Repeatedly pain and friction in the left side indicated the presence of a pleurisy: towards the end of the case a little dropsy, with slight albuminuria, supervened; and the termination was marked by hæmoptysis lasting a few days. The physical signs always pointed to an enlarged aorta, but there was no pulsation over this area, and the pulsation felt under the left clavicle on the first admission ceased to be perceptible; the pulsation in the jugular notch became much less, and the murmurs shifted their position of maximum intensity, so that the diastolic murmur was heard best to the left of the cardiac dulness instead of over the sternum, as before. The pupils continued all through the three residences to show at times a slight inequality, the left being the larger. With these changes in the physical signs, without anything more than a temporary amelioration, the idea of aneurysm was still entertained, and it was supposed that it might have grown downward or backward, so as to remove it from, rather than approximate it to, the surface within reach. The lungs remained tolerably free from signs of any serious change; there had been the repeated pleurisy on the left side, there were frequently some bronchial râles, and towards the end the left lung seemed more implicated. No marked dulness and no great enfeeblement of the respiration were detected. About two months before death the patient thought he had contracted a cold, and there was more cough. This was noticed to have a laryngeal quality, and after the first violence of the cough subsided a laryngoscopic examination showed the left vocal cord to be paralysed. The larynx had been examined soon after his first admission, and found normal. This new symptom, still pointing to the left side, seemed to remove all the hesitation naturally felt up to this point in the diagnosis of aneurysm; this was now regarded as well established. The laryngeal symptoms persisted to the end, but examination of the parts by the mirror was only practised twice or thrice, owing to his weak condition.

[1] This opinion as to the action of atropine on the living eye is supported by the authority of von Graefe. See Dr. Argyll Robertson's paper already quoted, Edin. Med. Journal, vol. xiv., p. 705.

The post-mortem examination was made by Dr. Newman. The aneurysm so confidently looked for on the left side did not exist, there was, indeed, a dilated aorta, and even the beginning of a small pouching towards the right side just above the valves; this might, no doubt, have developed into a regular aneurysm, if the patient had lived, but it had evidently nothing to do with the laryngeal paralysis on the left side. The aortic valves were quite incompetent, much diseased, and very hard and calcareous; this no doubt accounted for the murmurs; the heart was enormously enlarged. The cause of the left-sided laryngeal paralysis seemed to be due to the state of the left lung, which was found adherent and of a brownish colour; it had the appearance of being compressed and shrunken. The recurrent laryngeal nerve was found to pass through a mass of enlarged glands, just at the arch of the aorta. These existed at the root of the left lung and in the posterior mediastinum. They were of a brownish colour, like the left lung itself, but were not hard. The larynx was somewhat congested.

The explanation of the laryngeal paralysis seemed to depend on the dragging downwards of the left recurrent nerve, due to the greatly enlarged heart, and favoured by the shrunken left lung; and this downward displacement might account for the lessened pulsation in the jugular fossa and under the left clavicle, as the case went on. The implication of the recurrent nerve in the glands cannot be wholly set aside, although their softness would no doubt lessen the chance of their causing irritation, or at least of producing paralysis. The inequality of the pupils was not of the degree or of the kind to warrant much stress being laid upon it, and may fairly be set down as an accidental occurrence, although when it concurred with laryngeal paralysis it was somewhat misleading.

The explanation of the laryngeal paralysis on the left side suggested above was the only plausible method of accounting for this misleading symptom which we could think of at the post-mortem examination. I did not then know that such a cause of laryngeal paralysis was actually recognised; but on mentioning the case at the time it occurred to Dr. John McIntyre, one of my former pupils, who has now devoted himself to laryngology, he told me that in the Vienna cliniques this view seemed to be so well recognised that the diagnosis of such a condition was frequently discussed at the examination of patients. I have not been able to lay my hand on any published statements on the subject, although I believe such records do exist. We must, therefore, bear in mind that the occurrence of laryngeal paralysis on one side, in the course of a case with symptoms pointing to the chest and strongly suggestive of aneurysm, does not necessarily imply the existence of aneurysmal disease or of thoracic tumour.

A COMBINED ICE AND ETHER-SPRAY FREEZING MICROTOME.

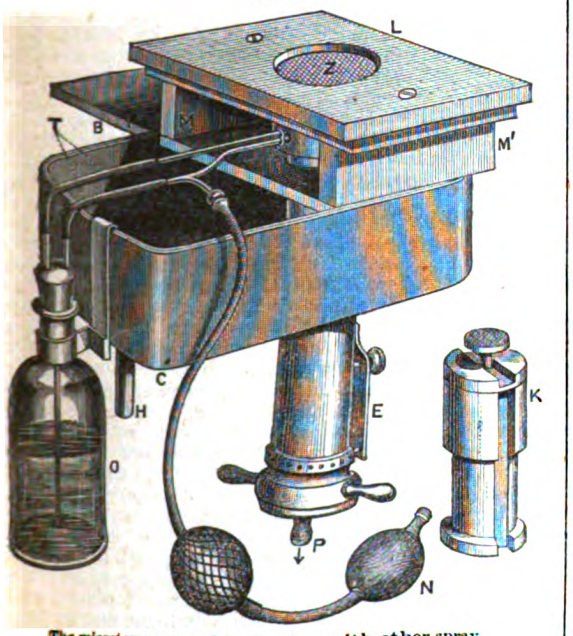
BY WILLIAM RUTHERFORD, M.D., F.R.S.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF EDINBURGH.

DURING the thirteen years that have elapsed since I invented the freezing microtome, the method of freezing has come into general use as an aid to microscopical research in physiology and pathology. It has also become of much service in aiding the practical study of these subjects, especially when they have to be taught to large numbers of students. The original ice and salt freezing microtome described by me in the *Journal of Anatomy and Physiology* for 1871, vol. v., was somewhat faulty. The improved form of the instrument (Fig. 2) described by me in THE LANCET, 1873, vol. ii., has been constantly used in my laboratory since that time. We have no difficulty in making with it from four to five hundred sections of the retina, kidney, or other organ, in the course of an hour. When large numbers of sections are required, it is, I think, always advisable to use a mixture of ice and salt as the freezing agent, on the ground of economy, and also because *large* pieces of tissue can be frozen quickly by it and kept frozen any length of time. We made a fair trial of the ice-freezing microtome devised by Williams and made by Swift of London, in the hope that its large freezing-box and method of regulating the thickness of the sections might

still further expedite the process of section making, but after a time we gladly returned to the use of my instrument, as more convenient and more reliable.

The first microtome in which ether spray was used as the freezing agent was invented by Dr. Bevan Lewis, and described in the *Journal of Anatomy and Physiology* for 1877, vol. xi. The principle of the ether-spray microtome is excellent when only a small number of sections are required, and the circumstance that the freezing agent is always at hand renders it very convenient; but it is not suitable when a thick piece of tissue is to be frozen and many sections made. I have found that even the modified ether-spray microtome described by Dr. Lewis in his work on the "Human Brain" (Churchill, 1882) leaves room for improvement. Eighteen months ago I added to my ice microtome an ether-spray apparatus for freezing, so that the instrument may be used as an ice microtome at one time and as an ether-spray microtome at another. (Fig. 1.) As the combined instrument is less costly than two separate instruments, and as the ether-spray arrangement differs in some particulars from any hitherto invented, I have thought that an account of it might help some of the readers of THE LANCET in carrying out their microscopical studies of normal and diseased tissue; and I may further help those who finished their medical studies before the

FIG. 1.



The microtome arranged for freezing with ether spray.

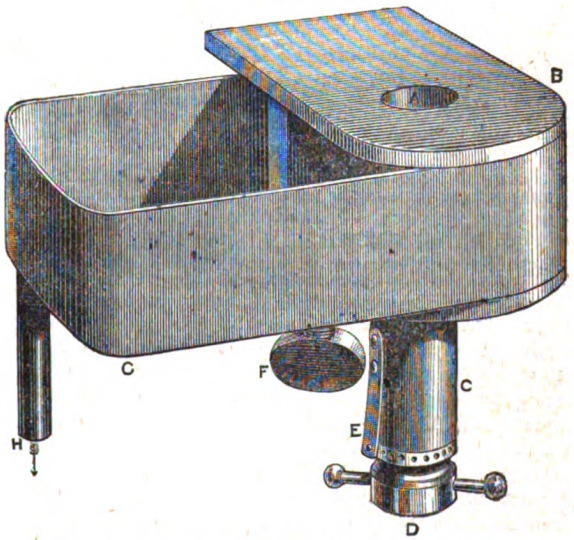
freezing microtome was invented, by briefly giving the chief details that must be attended to in using the instrument.

Preparation of the Tissue. — As a rule, the tissues should be steeped in the usual hardening agents mentioned in the books for three weeks or a month before they are sliced in the microtome. The prepared tissue should then be cut into pieces of desirable size and shape, and if it has been immersed in alcohol, every trace of that reagent must be removed by placing it for about six hours in a large jar of water. It is then transferred to a thick solution of gum arabic (gum one part, water two parts), in which it is left over-night, so that the tissue may be thoroughly permeated by the gum, to prevent it from becoming crystalline when frozen.

Use of the Microtome with Ether Spray.—The instrument is arranged as shown in Fig. 1. The tissue, which should not be more than a third of an inch thick, is laid on the roof of a zinc box (Z) and covered with gum. Ether, which must be anhydrous, is then blown from the bottle (O) by the elastic bellows (N) against the lower surface of the zinc plate. The condensed ether flows down through the tube (P), and is collected in a vessel. The spray-producing tubes (T) can be readily pulled out of the slot under Z for examination. The tissue is soon frozen, and it remains frozen for about five minutes in a cool room, without any further production of spray. The elastic pump can easily be connected with a sufficiently long piece of elastic tubing, and arranged on the floor in such a manner that, after the tissue is frozen, the freezing can be maintained by working the pump at intervals with the foot, thus leaving the hands free for the process of section-making. The zinc box on which the tissue is laid is insulated by vulcanite from the brass cylinder worked by the screw below it, and it is so made that, while ether is economised, a low temperature is obtained for a considerable time.

Use of the Microtome with Ice.—The glass plate (L) is unscrewed. The supports (M and M'), the tubes (T), the ether bottle and bellows, are removed; Z is unscrewed, and the plug (K) screwed in its place, and sunk deep in the well. The glass plate (L) is then screwed on the brass plate (B) and the instrument is ready for use (Fig. 2). Snow or finely pounded ice and salt are alternately placed in the freezing box (C) in small quantities, and stirred round the well with a piece of wood. A cork is placed in the tube (H) and removed only when the freezing box becomes full of water. Gum solution is poured into the well, and the tissue introduced, after a layer of ice has formed around the interior of the well, so that there may be no danger of any part of the tissue being without an envelope of frozen gum. The mouth of the well should then be covered with a thin sheet

FIG. 2.



The microtome arranged for freezing with ice and salt. (The glass plate screwed to the top of the instrument is not shown in the engraving.)

of gutta-percha, and a flat leaden weight placed on it. The whole instrument should then be enveloped in thick flannel, or some similar cloth, until the freezing is complete.

When arranged as shown in Fig. 2, the instrument can be used for the old method of embedding a tissue in melted paraffin and similar substances. In my laboratory the cutting of tissues by any but the freezing method has for years been abandoned in all cases excepting when sections are to be made without a machine. A great advantage resulting from the use of the method of freezing is that the embedding agent is readily got rid of by throwing and steeping in water for a time, leaving the most delicate tissues uninjured, and unencumbered by pieces of the embedding agent, as is the case when any embedding agent similar to paraffin is employed. Another important point is that the various methods for hardening the tissues so that microscopic slices of them may be sufficiently coherent for manipulation need not be pushed to the extent that was necessary when the tissue had to be cut embedded in paraffin. Consequently, finer preparations can now be obtained, and with an ease and certainty formerly unknown.

In making the sections with the above instrument the knife is pushed on the glass plate at a right angle across the well. I am aware that with this arrangement the knife does not remain sharp so long as is the case when it is not glided on any surface, but is supported at one or both ends of the blade by some framework. But I find it of great

advantage to have the knife held in the hand, so that it may be readily lifted and the sections quickly brushed with a goat's-hair brush into a basin of water, or, as in the case of the embryo, quickly drawn one by one from the knife laid flat upon a glass slip. Each section can thus be readily floated from the knife into a pool of water on the glass slip, so that every part of it is kept *in situ*. This ready handling of the sections in the mass or singly is impossible with the microtomes devised by Williams and Roy. Commonly the sections are brushed from the knife into a large jar of water, into which the gum diffuses from them. At the end of half an hour or so they are collected with a straight needle in small numbers at a time, and transferred to a second jar of water, in which they are left for the same time. They are then transferred to a third jar, and at the end of half an hour they are transferred in the same way to a stoppered bottle containing methylated spirit, in which they are kept till required for staining and mounting.

The indicator (E, Fig. 1), though useful to the beginner in helping him to make sections of uniform thickness, is soon abandoned, as the manipulator soon learns to regulate the extent of the screw's motion by his sensation. The knife suitable for my instrument requires to be specially made. Both instrument and knife are made by Gardner, instrument maker, South Bridge, Edinburgh.

AN EXAMINATION OF THE SUPPOSED ACTION EXERTED BY THE ANTAGONISM BETWEEN ACIDS AND ALKALIES IN MODIFYING THE TONICITY OF THE HEART AND ARTERIES.

BY SYDNEY RINGER, M.D., F.R.C.P.,
PROFESSOR OF MEDICINE IN UNIVERSITY COLLEGE, LONDON;
AND
DUDLEY BUXTON, M.D., M.R.C.P.,
ASSISTANT TO THE PROFESSOR OF MEDICINE IN UNIVERSITY COLLEGE, LONDON.

THERE are two forms of muscular contractility which are called into play during the functional activity of the heart and arteries: the one form is quick, of brief duration; while the other is persistent. This latter form is designated the tonicity of the heart muscle and arterial muscles. Although occurring in the same structure, these forms of contractility offer differences alike in nature and function. It is not our purpose at present to attempt to consider in what directions these differences in nature lie, or to attempt to analyse the mechanism of rhythm. In function, while the quick rhythmic contraction subserves the purpose of propelling the blood, the slow persistent contractility determines the actual capacity of the heart and vessels. Both forms of contractility are influenced by central and peripheral conditions. Thus the arteries can be contracted or dilated by central vaso-motor influences. Again, the arteries are subject to local or peripheral influences, which act either through a hypothetical vaso-motor controlling system situated in the vascular walls, or directly, as by the action of the circulating medium upon the muscular walls of the containing vessels.

Dr. Gaskell has shown[1] that acids and alkalies, when allowed to circulate in contact with the interior of the heart and arteries, exercise powerful influence upon their tonicity. His experiments are briefly as follows. To ascertain the action of dilute alkaline solutions upon the cardiac muscle, the frog's heart was removed from the body and fixed upon a perfusion cannula. To record the beat and obtain circulation through the heart, Roy's tonometer was used. Normal saline—i.e., ·75 per cent. of sodium chloride—was sent through the heart, and caustic soda was then added to the circulating fluid until it was of the strength of 1 in 20,000 salt solution. The heart very slowly and very steadily passed into systole—i.e., a condition of marked tonicity. A similar result followed when the same strength of caustic soda was added to artificial blood solution. Dr. Gaskell says:—"It is clear, then, from these two sets of experiments that a dilute alkaline solution acts upon the muscular tissue of the heart in such a way as to bring it from a position of relaxation to one of contraction, and that, according to the stage in this alteration of the contractile tissue, so will be the nature of the beat produced by the ventricle; the more the muscle is drawn together by the action of the alkali, the longer is the time of full contraction in each beat, meaning by the term full contraction the complete closure of the ventricular cavity." The next series of experiments, conducted on precisely similar lines, showed that were an acid—lactic acid, 1 in 20,000—used instead of the caustic soda, that the heart rapidly stopped, remaining in diastole. "The effect, in fact, is exactly the reverse to what took place with the alkaline solution." Dr. Gaskell then undertakes to show that the actions upon the heart of acid and alkali solutions are antagonistic. A heart brought to rest in systole by an alkali was completely relaxed by an acid from a condition of full contraction to one of extreme dilatation. The reverse experiment was also performed: a heart in relaxation by the action of the acid passed into extreme contraction when an alkaline fluid was circulated. Dr. Gaskell shows further "that alkaline and acid solutions act upon the muscles of the smaller arteries in the same way as upon the cardiac muscle." Dr. Gaskell concludes "that the one factor upon which the state of constriction of the muscles both of the heart and of the arteries depends is the extent of the alkalinity of the fluid surrounding them"; and, again, "one can say, then, that the presence of an alkaline fluid must tend to keep the cardiac and arterial muscles in a state of tonicity, and that upon the extent of the alkalinity the amount of tonicity will, at all events, in part depend." And, further, Dr. Gaskell seems to lean towards a theory which would explain varying degrees of tonicity by varying degrees of alkalinity, such being produced by an acid generated during muscular contraction, aided, possibly, by an acid liberated by other structures e.g., grey matter of the central nervous system during their function. The antagonism exercised upon the heart muscle is certainly proved, but how far the ingenious theory which hangs upon it can be accepted must at present remain unsettled.

We propose to show that substances other than acids may take on a *rôle* similar to the one performed by acids. Thus the salts of potassium can, as we have experimentally proved, act quite similarly to acids, in so far as antagonising the effects of sodium alkaline salts is concerned. Thus, we found, that when a circulatory fluid, composed of simple saline with the addition of caustic soda solution of the strength of 1 in 20,000, was allowed to flow through the heart arranged in the oil chamber of a Roy's tonometer, the heart passed into a condition of persistent systole. If, now, a physiological dose of potassium chloride—i.e., 1 in 10,000—was added, although the tonicity (spasm) of the heart was lessened, the heart was not enabled to pass into a state of complete dilatation—that is, the tonicity persisted to a certain extent. Our next experiments were conducted with the bicarbonate of sodium, this salt being used in place of caustic soda, for the following cogent reasons. Sodium hydrate, as such, does not exist in the serum or corpuscles of the blood, while bicarbonate of sodium is present in considerable quantity.[2] Caustic soda, then, possesses properties which, as we shall show in the sequel, are due to attributes other than its alkalinity. A normally beating heart being taken, and the saline solution being circulated through it as before, a quantity of bicarbonate of sodium was added, equal in strength to 1 in 5000. The effect of this dose was soon apparent. The beat, which had under the influence of the simple saline solution sunk almost to *nil*, recommenced, and the heart rapidly passed into a state of persistent systole, induced partly by the increased tonicity and partly by the fusion of the beats. In subsequent experiments even larger doses of the sodium bicarbonate were employed, and it was found that the condition of tonicity (persistent spasm) was produced so much the more quickly as was the dose increased.

To return. When the heart was finally contracted a high degree of tonicity being fully established, potassium chloride was added in physiological doses (1 in 10,000). In every case the ventricle underwent complete relaxation—*potassium chloride completely counteracted the effect of the sodium bicarbonate*,—tonicity of the heart muscle giving place to relaxation, the rhythmic contractions persisting. To test this antagonism

[1] Journal of Physiology, vol. iii., p. 48 et seq.

[2] Gamgee's Physiological Chemistry, p. 66.

…shown as large a quantity of sodium bicarbonate as 1 in 200 was used—i.e., a dose very largely above the proportion of sodium bicarbonate existing in the blood when that fluid is physiological. When the effect of the sodium salt was well marked and a pronounced condition of tonicity was established, 3 cc. of the potassium salt (1 per cent.) were added to the 200 cc. of the fluid—i.e., about 1 in 6000,—with the result that complete relaxation of the induced tonicity ensued. The addition of 1 cc. more of the potassium chloride, making the proportion about 1 in 5000, produced no further effect. It is needless to enter in detail into the subsequent experiments; they showed conclusively that: 1 the addition of the potassium salt can prevent the appearance of tonicity even when large doses of sodium bicarbonate are present; doses far larger than exist in the blood physiologically or could be administered therapeutically; and (2) the tonicity once induced by sodium bicarbonate can be completely overcome, relaxation replacing it when potassium chloride is added in physiological doses.

It would, then, appear from our researches that even if the alkalinity be a factor in promoting cardiac and vascular tonicity, and we shall return to the consideration of that question immediately, it cannot, however be asserted that the presence of an acid or acid tendency is the physiological antagonist in the body whereby cardiac tonicity is lessened or annulled. All that can be asserted, it appears to us, is that the hypothetic production of an acid condition, or rather of a less pronounced alkaline condition of the blood, may be instrumental in lessening cardiac tonicity.

We have in the experiments narrated above shown that potassium salts can actually prevent the occurrence of cardiac tonicity, even when such a large quantity of alkaline sodium bicarbonate is present as is competent, when unopposed, to induce a condition of extreme cardiac tonicity; and we are warranted by the fact that such potassium salts are present in large quantity in the blood and parenchymatous tissues, in saying that the bicarbonate of sodium cannot be accredited with the power of inducing constriction of the heart and vessels. But in order that we may deal with the problem involved in the action and antagonism between acids and alkalies, it is essential that we should place before us the physiological conditions which are present in the blood, and, as far as may be, reproduce them in our experiment. And we must make due allowance in deductions drawn from our results for departures from the physiological standard. It becomes, then, at once evident that the sodium bicarbonate which is found in the plasma could not induce tonicity either in the heart or vessels, its tendency in that direction being completely held in check by the chloride of potassium which, up on Lehmann's, Schmidt's, or Serlini's analyses,[3] is present in far larger quantities than those employed by us to counteract the sodium bicarbonate. From the above facts and considerations we conclude that variations in the alkalinity of the blood must exercise very little, if any, influence upon the tonicity of the bloodvessels and heart. But with the theory that arterial and cardiac tonus depend upon the alkalinity of the circulating medium is coupled one which would explain rhythm as resulting from an alternating degree of more or less alkalinity. It would then be admitted that our experiments completely subvert such a theory, rendering it wholly untenable.

Further investigations, indeed, have tended to make us believe that the "alkalinity" as such plays a far less important part in the induction of tonicity of the heart and vessels than has been heretofore supposed. Another possible explanation offers itself—viz., that the action of the sodium bicarbonate of sodium upon the muscle causing the relation called tonicity is at bottom a *sodium* effect. On this supposition we should expect to find that as the sodium became more or less chemically saturated, so would its effects become less or more marked. And such seems to be the case, for we may, without insisting further upon this point, one really of no important bearing upon the main facts of our present investigation,—instance the behaviour of the hydrate of sodium with the bicarbonate of the same metal.

We further undertook experiments to clear up the question whether the alkalinity was the true factor at work, and we found it was not so. When the heart was supplied with normal saline, massive doses of bicarbonate of sodium were added until the circulating fluid was rendered strongly alkaline, as judged by the bluing of red litmus paper. Tonicity or persistent spasm was developed, but when chloride of potassium was added the heart relaxed. An extremely dilute solution of caustic soda (1 in 40,000) was then taken. Its reaction to red litmus paper revealed that it possessed but feeble alkalinity; nevertheless it provoked the condition of persistent spasm or tonicity, and the heart thus treated did not become so completely relaxed, even when large doses of chloride of potassium were added. As, however, the blood possesses in its sodium phosphate a possible source of alkalinity other than the sodium bicarbonate, we instituted experiments with that salt. The solution which we employed was strongly alkaline. In physiological quantities we found the phosphate of sodium exercised no influence over the heart muscle, nor were marked results obtained with solutions which gave a strongly alkaline reaction. When, however, the sodium phosphate was pushed so that as huge a dose as 1 in 50 of artificial blood solution was reached some fusion with possibly increased tonicity of the heart were apparent. It is highly significant, however, to note that even in this extreme case, the addition of more potassium chloride removed the tendency alike to fusion of beat and increased tonicity of the heart. When the sodium phosphate was used with simple saline solution, we found that for a time it increased the vigour of the beat but produced little increase in cardiac tonicity, and such as appeared was promptly suppressed when potassium chloride in physiological doses was added. These experiments add further evidence that solutions, although strongly alkaline, do not necessarily increase cardiac tonicity. They show also that both the salts of the blood which are usually stated to give to that fluid its alkaline reaction, are completely overridden by potassium chloride, in so far at least as they are operative in inducing an increment in cardiac tonicity.

In experiments the results of which appear in the Transactions of the Royal Medico-Chirurgical Society, vol. lxvii., p. 78, it was shown that even highly alkaline solutions of the sodium bicarbonate do not as such determine constriction—that is, tonicity of the bloodvessels. Thus, as for the heart so for the bloodvessels, we find there are bodies which promote tonus, and that although some alkaline salts are included among them, yet there are others which oppose tonicity.

To sum up, then, we find from our experiments that the tonicity of the heart and vessels produced by alkaline solutions of sodium salts, such as are present in normal blood, will not only not appear in the presence of an acid, but will not be induced in the presence of potassium chloride; thence it is inconceivable how, in the teeth of the fact that large quantities of this salt potassium chloride—exist in the blood, the tonicity of the heart and arteries can be due to varying degrees of alkalinity. And we further find the alkalinity of the solution does not determine its power of producing tonicity in the muscles of the heart and smaller vessels, and so we suggest that this result may accrue from the degree of chemical saturation of the sodium present in the sodium salt.

[3] Quoted by Gamgee: Physiological Chemistry, p. 69.

TWO CASES OF GASTROTOMY FOR EXTRA-UTERINE GESTATION.

BY JAMES BRAITHWAITE, M.D. LOND.,

LECTURER ON DISEASES OF WOMEN AND CHILDREN AT THE LEEDS SCHOOL OF MEDICINE, AND SURGEON TO THE WOMEN AND CHILDREN'S HOSPITAL.

CASE 1.—Mrs. A——, when three months advanced in her third pregnancy, was seized with severe pelvic pain, so severe that it was necessary to administer morphia hypodermically. The whole of the remainder of her pregnancy was passed in misery from pain and sickness, with obstinate constipation. Towards the end of the pregnancy her medical attendant, Dr. Green of Leeds, convinced himself that it was a case of abdominal extra-uterine gestation. He could distinctly make out the position of the child through the abdominal walls. I saw the patient with Dr. Green a fortnight after the occurrence of a sanguineous vaginal discharge with some pain, which indicated that the uterus had thrown off the deciduous membrane. I need not say that when this occurs the death of the child may be considered certain. I found the patient in a very low con-

dition and looking worn from prolonged suffering. The position of the child could be readily made out, showing that no placenta intervened; a very important matter as regards the success of an operation. The cervix uteri was widely open and trumpet-shaped. The first two fingers of the left hand could be readily passed quite up to the fundus, the uterus being only three inches in length. Of course the only question was, What to do with the patient? for there could be no doubt as to the diagnosis. We decided to remove the child at once, as the condition of the patient could not admit of delay. This was done on May 5th, 1883. The incision was central; no peritoneum was met with, and the sac was closely adherent to the abdominal walls. The child was lifted out by its feet, but it proved so large that it was necessary to extend the incision upwards another inch. This unfortunately detached the cyst from the abdominal wall, and a coil of bowel protruded into view at the upper part of the wound. The cyst was carefully stitched to the lower surface of the wound with a continuous catgut suture. The placenta was deeply situated, but to what part it was attached was not positively ascertained. The cyst was of considerable thickness, already black from decomposition and lined with a smooth shining membrane (the amnion), which readily peeled off. After washing out the cavity with warm carbolic water the wound was closed with silver wire sutures, the cord being left hanging out at the lower end of the wound. A large glass drainage-tube was also inserted. During the next three weeks the whole of the placenta came away through the lower part of the wound. The cyst came with it, and I recognised the catgut which had been used at the upper margin of the abdominal wall incision. Much of the black and putrid mass was removed by daily traction upon the projecting parts, but unless great care was used hæmorrhage occurred. When the whole of the placenta and cyst had come away, the wound healed up rapidly, and the patient made a good though slow recovery, and she is at the present time as well as she was before her illness.

CASE 2.—Mrs. W——, of Holbeck, a patient of Dr. Dobson's, with whom I saw her in September last year, aged thirty-five, has been married ten years, but never pregnant until the present case occurred. Menstruation all her life quite regular and natural; the last period was about Oct. 15th, 1883. On Dec. 3rd, having missed exactly seven weeks, she was slightly unwell, and had at the same time, to use her own words, "a very violent pain" in the body. The symptoms were such as would be produced by rupture of an early tubal gestation viz., pain and collapse. She recovered from this, but the body went on increasing in size just as in normal pregnancy. At the end of August a sanguinolent discharge occurred, and this may therefore be taken as the time when labour would have taken place had gestation been uterine. The movements of the child, however, ceased to be felt about the end of the first week in August. By examination of the abdomen the outlines of the child were not perceptible as in the last case, but some thick substance intervened, which subsequently turned out to be the placenta. This much increased our difficulty in the diagnosis. There was a projection outwards of the abdominal walls in the right inguinal region, which felt not unlike a foot. There were no fœtal or placental sounds audible. The uterus measured only two inches and three-quarters and the cervix was well open, so that the finger could be passed up to, but not through, the os internum. The pulse was weak, and the condition of the patient such that, being quite certain it was a case of abdominal extra-uterine gestation, we decided to remove the child at once. This was done on Sept. 11th 1884 at the Women and Children's Hospital. The incision was central, and we came, as expected, directly upon the placenta, the edge of which, however, was found about two inches to the right of the incision. Careful separation of the placenta in this direction did not produce hæmorrhage. An incision at right angles to the first was now made, and the edge of the placenta being pushed back the feet of the child were seized, and it was removed without much difficulty, the placenta yielding to the pressure without being torn or separated from its attachment to the abdominal walls. It seemed to me that a single layer of peritoneum intervened between the placenta and the abdominal wall. This was carefully divided upon a director. This was no doubt the peritoneum proper to the abdominal wall. Whether the child was enclosed in a cyst or not we were not quite certain at the time of the operation; but, as proved afterwards, this was the case. There were no veins in the abdominal walls at the seat of the placental attachment except just at the lowest angle of the central incision. These I was careful to avoid wounding; they were, however, only of small size. The wound was closed with silver wire, the funis being left out, and a drainage-tube inserted, both at the extreme right of the lateral incision. An attempt to separate the placenta with the finger and traction in about two weeks set up hæmorrhage, and it was not attempted again until the discharge became very decidedly purulent at the end of six weeks. The whole of the placenta which had not been removed, for some small portions had been, was at the end of six weeks separated by the finger and removed without much difficulty. It weighed thirteen ounces. The patient is still in the hospital, but is nearly well. In introducing the finger for removal of the placenta I felt the cyst walls, which appeared to be pretty firm and thick.

The first thing worth remarking in the history of these cases is the occurrence of severe pain early in gestation, attended with some degree of collapse. This indicated rupture of the Fallopian tube, in which, up to that period, the fœtus had resided, and its escape in the first case into the interior of the broad ligament, and in the second into the peritoneal cavity. I assume that the explanation of these cases given by Mr. Lawson Tait is the correct one, and I believe it to be so—namely, that all cases are originally tubal, that rupture always occurs, but that this rupture may be in different parts of the tube; if on the lower surface of the tube the fœtus is let down between the folds of the broad ligament, and then develops, the placenta retaining its original hold upon the interior of the tubal cyst; if the tube ruptures on its upper surface the fœtus escapes into the peritoneal cavity; and if the mother survives it develops there just as it would have done in the uterus. It seems pretty clear that in my second case the placenta was detached from its original position and took root again in a fresh one, and that the interior of the abdominal walls. This situation of the placenta is rare, and I think it may without much difficulty be diagnosed by the thickness of the structures intervening between the fœtus and the examining hand.

The first case would be called one of subperitoneal pregnancy, because the peritoneal cavity was altogether external to the fœtus and its cyst. The course of the peritoneum at the time of operation would be down the abdominal parietes to the umbilicus, then reflected upwards over the anterior surface of the upper part of the cyst, then over its summit and down its posterior surface, so that up to the level of the umbilicus the peritoneum had been separated from the abdominal walls by the growth of the child upwards; whilst above the umbilicus the cyst covered with peritoneum projected into the peritoneal cavity.

In the second case the child was contained in a false cyst, composed of a fibrinous effusion, which shut it off completely from the peritoneal cavity. This, however, is not necessarily present in intra-peritoneal pregnancy, and the child may be found loose in the peritoneal cavity. It is worth remarking that if the peritoneum is not stripped upwards with the growth of the fœtus in subperitoneal or extra-peritoneal pregnancy, the cyst is found covered with peritoneum anteriorly, just like an ovarian cyst. An instance of this is the case related by Dr. Heywood Smith,[1] in which a thin cyst was found not adherent to the abdominal walls and covered with peritoneum.

It is very remarkable that in the first case the cyst itself died at the same time, or about the same time, as the child and the placenta; for it was found black at the time of operation, and was subsequently thrown off with the placenta. *A priori*, one might have supposed that such a thick cyst would have retained its vitality. Probably its contact with the dead placenta accounts for this. In the second case the cyst did not die, although its vascular supply must have been insignificant, or absent altogether; whereas the vascular supply of the first cyst must have been very considerable.

It seems to me a remarkable thing that when the cyst and placenta in the first case formed a black sloughing mass, which was directly in contact with the peritoneum externally, there were no signs of peritonitis or septicæmia. No doubt the external surface of the peritoneum has different properties from those of the internal and more absorbent one.

SCHOOL WORK AND DISCIPLINE AS A FACTOR IN CHOREA.

BY OCTAVIUS STURGES, M.D.,
PHYSICIAN TO THE WESTMINSTER HOSPITAL AND THE HOSPITAL FOR SICK CHILDREN.

In an analysis of 200 examples of chorea which have been under my own care during the last ten years, there are as many as 121 where—either because there is an absence of all apparent exciting cause, or else (and this more frequently) because there is room for contention as to which of several events ought properly to occupy that place—the actual mode of origin of the affection is left in doubt. There remain seventy-nine cases of known causation, and of these fourteen were due to schooling. In other words, a continuous observation, embracing a large number of cases and excluding those which are uncertain or equivocal, finds one in six to represent approximately the proportion of children suffering in this particular way, owing to circumstances directly connected with their education.

It is true that these figures must not be rigidly insisted on. On the one hand, it is to be remembered that not all of the 200 are in the pupil state; on the other, that the chorea of schooling, or (to be in harmony with a well-worn expression which the subject suggests) of over-schooling, is pretty certain to appear as such, while the chorea from other kinds of nervous shock to which children are peculiarly liable is very likely indeed to seem spontaneous. No doubt the fourteen sufferers I have named ought to be taken from a larger number than seventy-nine; still there they are. School training is responsible in greater or less degree for chorea; it is responsible for it in a degree which, by comparison with other causes, is not inconsiderable.

But it is said it is not the schooling that should be blamed, but the underfed condition of the scholars. And in favour of that view it may be urged that chorea is a disease of the poor rather than of the rich. But it is not by preference a disease of the very poor. No one, I think, with large experience of sick children would say that this affection belongs to the group which we learn to associate with extreme poverty and neglect. Chorea is a disease of the poor because, speaking generally, the poor are less careful and observant and more happy-go-lucky than the rest of us as regards both themselves and their children. It is a disease of the London poor because crowded streets and railways and overcrowded dwellings afford abundant occasions of alarm and disquiet, and because, other things being equal, the London child is feebler and less able to cope with its surroundings than the country child.

During the last six months as many as eighteen examples of chorea (not included among those just quoted) have been admitted under my care to the Hospital for Sick Children. In nine of them various reasons are assigned for the affection, which on inquiry appear to be veritable exciting causes. In six it is school work which figures in this relation. Two of these are girls who had been excited and sleepless in prospect of a school examination, one of them having moreover received a severe caning for being late, which left its mark for some days. Of a third girl, a pale, frail, child of eleven, in the sixth standard, who for a month before had complained of pains in the head and heart, it was alleged that she was kept at her lessons every day, including meal time, up to nine o'clock, and had had no time for play for months. In a fourth instance, a boy aged ten got chorea quite suddenly whilst in school after a caning on his hand. It was a second attack; the first had been due to a drunken man falling upon him. The two that remain had been "bothered" over schooling and sums, and to one of these I will refer more particularly presently. There are, besides, a child who had been run over in the street, one who had been frightened by seeing a mad dog shot, and a girl of eleven, already choreic, but allowed to run up and about, who became much worse on seeing a boy kill a kitten in a very cruel manner. The list serves to illustrate the injurious effect upon poor children, not only of excessive school work, but of naked exposure to the dangers and brutality of a crowded city. It is remarkable that all the patients save one are girls.

And not only may school operate injuriously upon children apart from any particular error or deprivation in the way of food, it is even possible to classify and to graduate the mischief done in this particular way. There are the excitement and mental strain produced by competition; there are the effect and the fear of school punishment; and there are the worry, disappointment, and despair over lessons that are too hard or too many. Such causes will sometimes of themselves produce chorea; and sometimes, and perhaps more often, they will bring about such nervous instability that the least additional strain will show itself in that way. The severest and most rapidly fatal case of chorea I ever met with was that of a girl, a pupil teacher, who, on her way to an examination, the prospect of which had excited her very much, was still further disturbed by a carriage accident, in itself quite trivial.

Apart from combined causes of this sort, which do not now concern us, there is the question as to which of all the various rigours of over-schooling is the most effectual in the production of chorea. If I were called upon to answer that question in a single word, experience would teach me to say *sums*. In the two patients just mentioned, where the worry of school work is the alleged exciting cause, the particular form of the trouble in both is ciphering. One of these children, indeed, so well illustrates the way in which this comes about in scores of similar cases that in spite of its apparent triviality it is really instructive, and I may be pardoned for quoting it. This girl, aged nine, healthy and ruddy, but of excitable temperament, is stated by her mother to have been troubled and sleepless owing to school lessons, and especially sums. The choreic movements are slight, but general, and the voluntary muscles still within control. Some days after admission, when the child is first questioned on the subject, the mention of sums at once excites weeping. This form of emotion, it may be said by the way, is an excellent criterion for use in chorea. Children will readily assent to whatever is stated of them, and mothers are prompt and ingenious to discover causes for an affection of this kind, which is still overladen with superstition in the minds of the ignorant. But when bare mention of some actual incident—a beating, or a dark cupboard, or a strange dog, or some school hardship—occasions a flood of tears there need be little doubt, I think, that we have reached the real, although of course not necessarily the sole, source of the malady. In the present instance, so soon as the first outburst was over, the child was willing to enter into details. The particular form of her affection was long division, or what she called simply "division." Short division she had never known, it had been skipped. And it might very well have been, as the child herself seemed to think, that the sudden transition from subtraction to long division, due to some unexplained accident, was the beginning of all the trouble. As evidence of her capacity the child worked a sum in long division before us sitting up in bed. It is an operation familiar enough, I suppose, to teachers, but curious and suggestive to watch where the performer is a nervous and choreic child. The method employed was no doubt that which had been taught, and it was this. The left arm is clutched round the slate, the fingers being hooked to its right upper corner, and it is maintained in writing position by being pressed against the pit of the stomach. Face, lips, and tongue concur with the right hand in the work to be done. The slate pencil is held low, and, the tip of the forefinger being always moist, figures in the immediate vicinity of writing operations are in danger of getting accidentally rubbed out. This is particularly the case at the moment when, to signalise the fact that a figure has been brought down from the dividend, a little cross is made just above it. At the slightest suggestion of error the work is suspended, the finger rewetted, and the doubted number rubbed out. From the frequency of such erasures and the mode of effecting them, the working surface of the slate becomes wet and sticky, insomuch that it presently ceases to afford sure holding for the pencil point. In the bad places, indeed, owing to repeated correction, there is a confused mixture of saliva and pencil mark which can no more be written upon than a coat of varnish. The seriousness and persistence with which the child encounters all these difficulties, the conscientious completion of each figure and prompt wetting of the finger to score it out, the cheerfulness and alacrity displayed when the time comes for some formal and obvious act, such as drawing lines and affixing crosses, the way in which severity of mental conflict is shown by a tighter grasp upon the slate and increased pressure upon the stomach—all this makes a picture which to the un-

initiated is half comical and half touching. This child was working her sum in long division in bed and before indulgent critics. I am told it is the custom at some schools to stand round in a class and work sums at a uniform rate by word of command. Suppose a child, like this patient of ours, to have been already harassed and haunted by sums and driven to the verge of chorea, her hands and feet restless and unruly. Then suppose her standing in class, with heels together in the "first position," ciphering. Is there any kind of work that can be thought of so admirably contrived to develop the complaint we are considering?

From this point of view, indeed, it is not the patient that is to be pitied, it is the poor child who is working up to that condition and qualifying for chorea by daily endurance, failure, and penalty. Once the affection declares itself, and there is an end to all this suffering. The defaulting scholar becomes the indulged patient, happy enough if only left to such rest as she can command, and not troubled about coördination. Chorea comes as a friend. Yet it is amazing how long it will remain unrecognised; how, almost habitually, the characteristic movements of an affection, which ought to be familiar to every teacher and parent, are at the first mistaken for awkwardness or perversity.

And this brings me to the object and end of this paper. We write about these things, but we cannot mend them much. Sums will be worked in the new year much as they were in the old, children will be brought prematurely into long division, the pressure of schooling will be ill adjusted, here too much and there too little, teachers will be impatient and exacting or lax and negligent, just as before. We must not expect too much. Yet what a world of suffering might be saved suffering which is in the highest degree cruel and unjust—if every school teacher, and especially those in London, were required to know the more obvious signs of St. Vitus's dance; know them, I mean, not as we do, but sufficiently to be able to pick out for skilled examination such children as have suspicious symptoms. All children are fidgety, and all fidgetiness is not chorea; yet any signs of extra fidgetiness, any manual defects which are new and striking, ought always to suggest chorea and to lead to inquiry. This is more especially the case when the child has just been put into a higher class or into a new rule of arithmetic, or when she is in training for examination. When the careful child becomes careless or the dexterous awkward, when writing suddenly deteriorates or place in class is repeatedly lost, when slates and books are much dropped, or there is obvious facial movement in writing and reading, in all such cases I do not say there is chorea, for natural perversity and "temper" have to be taken into account, but I say there is ground for that suspicion, and particularly with girls and those who have had the disease before.

We hear sometimes regrets expressed that disease has been suffered to run its course to a fatal termination, and that the doctor has been called in too late. And we have to admit that from the nature of the malady no medical aid would have been of much avail. With chorea the case is different. There is little enough of danger in it, but such as there is arises from the fact that helpless children, unable to express themselves, and even with a sort of belief that their involuntary errors are really of the nature of sin, are left for an indefinite time exposed to all the hardship and rebuke which their condition entails. All this may be prevented and a vast amount of child suffering spared, if only we can teach the teachers how to observe.

Wimpole-street, W.

CASE OF EPILEPTIFORM SEIZURES, WITH UNUSUALLY SLOW PULSE.

BY F. ST. GEORGE MIVART, F.R.C.S. ED.,
SURGEON TO THE WESTERN GENERAL DISPENSARY.

J. K——, aged sixty-one, a "caretaker." Has served in the army (never out of England), and also in the police force, particularly the police department of the Excise. No history of neuroses in his family. Has never had syphilis or acute rheumatism. Has always been temperate, and on the whole has enjoyed moderate health, except that, to use his own words, "he has suffered from his heart." He himself refers this to hard work and long hours of exposure to cold and wet while in the police force, and remembers being much troubled at times while on duty by the throbbing of his heart. Since then until within the last few years he has frequently suffered from palpitation, which has usually come on at night, and sometimes has been so severe as to shake him in his bed. On these occasions he could generally feel his heart beating rapidly. He never had a fit of any sort until six years ago while working in a garden, when he appears to have had one fit of an epileptoid character and short duration. Two years later he had another fit of a similar character. Both these attacks came on when he was stooping forward with his head low down. He has noticed that stooping always makes him very giddy, and he has consequently avoided that posture as much as possible. His next attack was on the 23rd of March last. While sitting on a chair his wife says she saw him suddenly fall forward, and he had then three fits in succession, apparently of the *petit mal* variety. He would seem by the description given me to have been much cyanosed. On all these occasions before the seizure he was conscious of a buzzing sensation in his head. I saw him on the following day. He was then in bed, unable to stand, complaining of giddiness and a feeling of confusion, also a sense of constriction at the chest with difficulty of breathing. He is a tall, well-built man, but looks flabby and anæmic. Pupils equal and normal; urine and temperature both natural; tongue a good deal coated, bowels confined; pulse regular, tolerably firm and full between the beats, which are at the rate of only twenty per minute; heart's impulse almost imperceptible except very faint movement at the tip of the sternum. The presence of sibilant rhonchi and wheezings renders the auscultation of the heart a little difficult, but apparently there is only one sound audible accompanied by a bruit, heard best towards the apex. The sound of heart is synchronous with the radial pulse. Owing to the patient's employer being anxious for his removal I was unable to visit him again for some weeks, as he was taken to a remote suburb. I saw him again on the 18th of April, nearly a month after my first visit. He said he felt better. He had had no more fits, though he still felt very giddy on any sudden movement. In appearance he is more markedly anæmic than before. I examined him both in the erect and recumbent positions, and in each the pulse-rate was the same viz., 24,—while the artery was still firm and full. In the erect posture I found his cardiac sounds more audible, and was able to detect a soft systolic bruit somewhat like a prolonged first sound at the apex and round towards the axilla. I could also distinguish an apparently aortic systolic murmur. The impulse of the heart was more perceptible; the urine was dark coloured, acid, sp. gr. 1018; and the potassio-mercuric iodide test showed a trace of albumen. On visiting the patient a month later I found the physical signs unchanged, but he says he feels decidedly better, and he can now walk from room to room. His pulse-rate is still the same—viz., 24 beats per minute,—but after walking up and down the room several times it rose to 26. I very much regret I have never had an opportunity of examining the pulse during a seizure.

The question, of course, arises as to whether the seizures were really epileptic. That they partook largely of a syncopal character cannot, I think, be doubted, and the distinctly cardiac history of the case points to this. The decreased impulse of the heart makes it probable that the aortic murmur is due to atheromatous deposit about the valves. Possibly, also, there may be some aortic stenosis, and there can be little doubt that the heart is fatty. This being so, more or less anæmia of the brain is not unlikely, and attacks of syncope from this cause can be understood. "Between syncopal attacks and those of minor epilepsy," says Dr. Russell Reynolds, "there is perhaps a much closer analogy than is generally supposed." Now, there was undoubtedly a considerable epileptic element in the attacks described. My idea is that the seizures were simply swoons modified by the patient's epileptic tendency.

Green-street, Grosvenor-square, W.

DAVIS, the fireman, who was seriously injured in the railway collision between a Great Eastern and a Midland train, near Camden-road, on Monday night, died in the Royal Free Hospital, Gray's-inn-road, on the 30th ult. He was suffering from a compound fracture of the skull, and was in a semi-unconscious condition from the time of his admission until his death.

ON LIFE-SAVING FROM DROWNING BY SELF-INFLATION.

BY HENRY R. SILVESTER, M.D., B.A. LOND.,
FOTHERGILL MEDALIST, ROYAL HUMANE SOCIETY.

"He long survives who lives an hour
In ocean, self upheld;
And so long he, with unspent power,
His destiny repelled;
And ever as the minutes flew,
Entreated help, or cried 'Adieu!'" COWPER.

THE reduction of the specific gravity of animal bodies by means of hypodermic inflation is a subject which has for some time engaged my attention. I have endeavoured to elucidate it by an experimental inquiry, my object being to diminish the great mortality from drowning. From the earliest ages attempts have been made to render the human body capable of floating in water, but these efforts have mainly been in the direction of attaching to the body, when immersed, various substances of less specific gravity—such, for instance, as the inflated skins of animals, life belts, &c. Atmospheric air, from its extreme lightness, —namely, 815 times lighter than water—has been most frequently employed, but there has been some difficulty in finding a suitable envelope for containing it. It is atmospheric air which is universally employed by nature to produce buoyancy. Many fishes possess hollow sacs filled with air, and these sacs are developed occasionally from the ventral, though more commonly from the dorsal wall of the pharynx, œsophagus, or stomach. In the Teleostei the membrane lining the branchial chamber is prolonged into sacs, which lie at the sides of the body. The Diodons and Tetrodons render themselves buoyant by swallowing air, which filling the first stomach, they become inflated like a balloon. In the case of birds there are in some as many as nine air sacs, two of which are situated in the cervical region, whilst in some of the Lacertilia the membrane of the larynx between the circular cartilage and the first ring of the trachea protrudes in the form of an air sac.

It will be within the recollection of your readers[1] that I have already demonstrated at the International Fisheries Exhibition the possibility of inflating the subcutaneous space in animals so as to render them sufficiently buoyant to be employed either singly or yoked together to convey persons from a wreck to the coast; but since animals are not always present in cases of shipwreck, and human lives may be saved by being enabled to traverse a few yards of deep water, I have demonstrated the possibility of producing in man himself the condition known as surgical emphysema. In August, 1883, at King's College Hospital, by means of a blowpipe and elastic syringe, I inflated at the wrist the subcutaneous tissue of the whole body with the result that in a few minutes sufficient air passed under the skin to support a weight in water of between forty and fifty pounds. This amount is considerably more than would be required to preserve a person from drowning, nine or ten pounds being considered sufficient. Although one can imagine the existence of circumstances which would justify such a proceeding as the above, yet the practice of it would require a certain amount of surgical knowledge. Moreover, it would be impracticable except under favourable circumstances; and there are probably few persons capable of accomplishing it in their own bodies. I have accordingly sought for a much easier and more ready means of rendering the body buoyant in water, and which could be accomplished without the employment of any apparatus, and, in fact, which might be performed without assistance in a moment, under the most adverse circumstances, and by the most ignorant, if once instructed in it, and without danger or pain, and suitable alike for the roughest sailor or the most delicate female. The intention of the proposed operation is to cause the skin of the neck and upper part of the chest to be sufficiently distended with air to support the weight of the body when immersed. The inflation being effected by the person on himself by means of his lungs without the intervention of appliances. The operation consists in making a small puncture—not larger than would allow, for instance, of the passage of an ordinary blowpipe—in the mucous membrane of the inside of the mouth, the object being to open a communication for the passage of air from the cavity of the mouth into the subcutaneous spaces of the neck. The situation chosen for the puncture is in the angle formed between the gum of the lower jaw and the side of the under lip or cheek, about opposite the first molar tooth of the lower jaw. The point of the instrument perforating should be passed down a short distance between the skin of the side of the face and the superficial fascia of the neck, its point being guided by the finger placed on the outside of the face and neck, taking care not to puncture either the skin or the superficial fascia. This having been done, and the instrument removed, in order to inflate the skin of the neck and chest, the patient should close the mouth and nose, and make a succession of forcible expiratory efforts, when the air contained in the cavity of the mouth will pass freely into the subcutaneous tissue of the neck. These expiratory efforts, inspiration being effected through the nostrils, should be continued until the skin is fully distended with air, which will pass readily to both sides of the neck and down the chest as far as the nipples; and this is all that is required to render the body buoyant in water. Should it so happen that the superficial fascia has been punctured and the air pass beneath it, the only difference in effect would be that the extent of air would be limited by the attachments of that membrane to the clavicle below and the border of the jaw above. The amount of air which the skin of the average neck is capable of holding without undue distension has been measured, and found to be enough to support ten pounds, and this is amply sufficient to support the body immersed in water. The time required for inflation is found to be less than three minutes. The neck may be kept in an inflated condition by closing the puncture by pressure on the outside of the cheek by the finger, or by keeping the mouth distended with air; and when required the air may be immediately discharged from the neck by allowing the puncture to remain open, or by suction.

The advantages may be summed up as follow:—1. The proceeding is perfectly harmless and almost painless, quickly done, and almost immediately recovered from. 2. It may be learnt in a few minutes, no technical knowledge being required, and may be accomplished by the person himself without assistance. 3. No special apparatus is required. In an emergency the point of a penknife, or even a sharp pointed splinter of wood, is all that would be required. The inflating apparatus is the person's own lungs. 4. The air could be repeatedly reinflated, and even during prolonged immersion.

TRANSFUSION IN A CASE OF CHRONIC PHTHISIS.

BY T. W. CARMALT JONES, F.R.C.S. EDIN.,
SURGEON TO THE WESTERN OPHTHALMIC HOSPITAL.

ON May 14th of last year, in consultation with Mr. De Gruyther of Holloway, I saw Mr. C——, a diamond cutter, aged thirty-four. He had been suffering from phthisis for about nine years, but had been able on and off to go to work. Latterly he had found his strength failing and nine or ten weeks before I saw him he had given up work. For seven weeks he had not been outside the house, and for the last fortnight he had kept his bed continuously. He was then so weak that he was unable to get out of bed or to stand without assistance; the most he could do was to sit up in bed and get to the edge of it and let his legs hang down. He was very thin, the hands shrunken and the skin loose; the face was pale with a patch of pink colour on each cheek; the skin of the face looked sodden and clammy, though he said that he was never troubled with sweating, except after a bad fit of coughing. The expression was anxious; the fingers were clubbed; pulse 135, full and soft, but easily stopped; temperature 100°; breathing rapid with a rattling bubbling sound, audible across the room. By the bedside was a jampot half full of tenacious, purulent sputum, streaked with thin lines of bright blood. He said he had on several occasions brought up large quantities of blood. After examining the chest we agreed that there was a large cavity in the right apex, extensive consolidation, and possibly, also, a cavity in the left. The

heart was normal; no albumen in the urine, of which he passed about a pint and a half a day; but feet and ankles were slightly swollen. The bowels acted daily, motions formed, no blood. Tongue furred; mouth not aphthous. The abdomen was slightly prominent, but soft, not tender, and was resonant down the left side. He did not complain of pain or discomfort after food, or any other signs of dyspepsia. Mucous membranes of eyelids and lips were pale. The patient said he took his food well and enjoyed his meals. His habits appeared to be to have a cup of tea and a piece of toast about 6 A.M., a couple of fried eggs or some fish at 11, and to dine at 6 P.M. off a chop or steak. He did not like milk and did not take much of it. Sometimes he would take a glass or two of port. The friends thought there was very little hope for the patient, and, to use their own expression, wanted to know if we could "patch him up for a few weeks." Considering that the patient was so anæmic, but still had a considerable amount of vitality in him that he could take his food so well and was not being exhausted by night sweats, I suggested transfusion. The patient was willing to try anything, and his wife offered to give the blood.

The next day (May 15th), having procured an Aveling, with the assistance of Mr. De Gruyther and a sister of the patient I transfused about two ounces directly from a vein in the wife's arm to a vein in the patient's arm. During the process the patient exclaimed, "I feel so hot; open the door." The wife rather complicated matters by vomiting during the transfusion, and was rather faint afterwards; but the patient was in no way worse, and said he should be ready for his dinner at the usual time. On the 16th Mr. De Gruyther reported: "Patient is better to-day; his pulse seems to me to be improved, and is 120; he himself feels better." On the 19th I saw the patient, and found his pulse 128, but much less easily stopped than on the 14th. He had taken his food as usual, and said he felt stronger. He further said that on the 17th he had got out of bed and had walked across the room to an arm-chair without assistance, a thing he had not been able to do for a fortnight. The wounds in both cases looked well, and there were no signs of inflammation or tenderness over the course of the veins. On the 21st Mr. De Gruyther again reported: "Our patient is progressing very favourably; his pulse was about 120 to-day and firm; he walks without aid." On the 22nd, one week after transfusion, I saw the patient. I found him sitting in an arm-chair, having moved into the next room. He had walked from one room to the other without assistance. He looked much happier; the pulse was stronger and 128. He said he felt stronger, and that he was sure he should be better if he could only get some sleep, that he had hardly had any sleep from 9 P.M. till 5 A.M. the previous night on account of his cough. The patient's wound was almost well, the one in the wife's arm showed a small slough. On the 25th Mr. De Gruyther wrote: "Our patient had a weak pulse of 116 yesterday, and he himself felt weaker. He says he had a better night on Friday (May 23rd) after inhaling five minims of eucalyptus oil in a metal respirator. The slough from the wife's arm has not come away." On the 26th Mr. De Gruyther wrote: "Our patient is not so well to-day."

May 28th.—Thirteen days after transfusion I saw the patient. I found him setting on a couch in a room next his bedroom; he had walked there with difficulty, and with assistance. His expression was much more anxious; his pulse was 130, and very easily stopped; his appetite was very bad, and he could only take liquid nourishment, such as egg and milk or beef-tea. He had lately discovered that he could take milk. His ankles were swollen. I found that on Friday, the 23rd, he had walked by himself with ease down the passage of his house out into a small garden or yard at the back and had sat in the sun for some hours, and had thoroughly enjoyed it, and that he had slept better that night. On Saturday, the 24th, he had done the same thing again, but had walked with even greater ease, and had felt still stronger. Sunday, the 25th, was a cold day, and he did not go out. On Monday, the 26th, he had not felt so well; on Tuesday, the 27th, he had felt worse, and on Wednesday, the 28th, he had gone back considerably. The cough was still the great trouble, it prevented his resting; but the amount of sputum was considerably less than when first seen, and there had been no sign of blood in it since the transfusion. The wife complained of pain in her arm, the slough had come away, the wound was healthy and healing, but there was tenderness along the course of the median vein, and the vein was thickened and cordlike. On May 30th Mr. De Gruyther wrote: "Yesterday our patient was a good deal weaker; he took a fair amount of nourishment, and had better rest at night."

June 3rd.—I saw the patient, and found him on the couch; pulse stronger, 120. He would take no medicine of any kind; he looked happier again; his appetite was better, and he fully intended to go out into the garden again as soon as practicable.

June 12th.—The patient had been out in the garden several times since June 3rd, but he had gone back. Pulse 120, weak and small. Both legs were much swollen and œdematous. The abdomen measured thirty-one inches and a half; it was tense and full of fluid. Very little albumen in urine, but some dyspnœa at times. A day or two after this date the patient was taken in a cab to the German Hospital, where he remained until July 27th, when he died. I have not been able to hear whether there was a post-mortem or not, but I think it is most probable that it was not allowed.

ST. GEORGE'S HOSPITAL.

A CASE OF RUPTURE OF THE GLUTEAL ARTERY AND ONE OF AMPUTATION AT THE HIP-JOINT ILLUSTRATING MORE RECENT METHODS OF ARTERIAL COMPRESSION.

(Under the care of Mr. HAWARD.)

FOR the following notes we are indebted to Mr. R. Margerison, surgical registrar.

John D——, aged twenty-four, received in May last a blow on the right buttock from the buffer of a locomotive. When admitted soon afterwards into St. George's Hospital, the buttock presented near its most prominent part a contused and lacerated wound large enough to admit a finger. Out of the wound dark blood oozed very freely. The soft parts were very extensively undermined, and beneath them was a large and increasing collection of blood. This blood collection did not pulsate and no bruit was audible. A pad was firmly bandaged over the buttock for three hours. In this interval the collection of blood had greatly increased, and when the pad was removed large quantities escaped. Ether was then administered and the right iliac artery compressed with Davy's lever. When once introduced far enough, this instrument acted perfectly. Mr. Haward enlarged the wound to a length of some six inches. The gluteal muscles were found to be torn across, and beneath them existed a large cavity full of blood. This was quickly turned out, bringing into view the sciatic notch and the open mouth of the gluteal artery. This and a great many other muscular vessels were secured with catgut ligatures. No blood was lost during the operation and the man's recovery was uninterrupted.

The case shows well the value of the lever, and in connexion with this subject of compression of the large vessels of the abdomen it seems well to mention a case of amputation at the hip-joint for sarcomatous disease, which also occurred in Mr. Haward's practice. Here the abdominal aorta was very effectually controlled by a contrivance more or less like that suggested by Sir Joseph Lister. The blunted apex of a pyramidal piece of wood was fixed over the abdominal aorta by an elastic bandage. The apex of the pyramid was about one inch square and covered with felt. The base measured about three inches square and presented instead of a plane surface a broad and shallow groove. The elastic bandage passed round the pelvis and along this groove. When fixed it was placed in the charge of an assistant, who, grasping the wood with both hands, could very easily and

nicely direct and regulate the pressure. This contrivance caused no dyspnœa and completely checked all bleeding.

HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S-PARK.

SEQUEL TO THE CASE OF EXCISION OF A TUMOUR FROM THE BRAIN.

(Under the care of Dr. HUGHES BENNETT and Mr. RICKMAN J. GODLEE.)

IN our issue of Dec. 20th we supplied our readers with some notes of a case in which a tumour had been excised from the substance of the brain on Nov. 25th, with the condition of the patient up to the 15th ult.; to which date the progress of the case had been entirely satisfactory. We are now enabled to give the sequel, which has unfortunately terminated in the death of the patient. On the morning of Dec. 16th the man was suddenly seized with a rigor, followed by fever, sickness, and pain in the head. A hernia cerebri of large dimensions supervened. The pyrexia increased and continued, the patient emaciated, gradually sank, and died on Dec. 23rd, the intelligence remaining intact to the last.

On post-mortem examination meningitis was found at the lower border of the wound, spreading downwards towards the base of the brain on the same side, the whole of which was inflamed and covered with plastic lymph. With the exception of the loss of cerebral tissue, caused by the operation, the brain was otherwise practically normal. We understand that the details of this interesting case will be brought before the profession in due course.

DUNDEE ROYAL INFIRMARY.

ACUTE CEREBRAL MENINGITIS; RECOVERY.

(Under the care of Dr. SINCLAIR.)

FOR the following notes we are indebted to Dr. A. M. Stalker, pathologist, late house-surgeon:—

J. R——, aged eleven, mill-worker, was admitted on March 31st, 1882, suffering from an illness which had commenced five days before. There was no history of illness or injury previous to this. The symptoms were pain and stiffness in the neck, especially on the right side, with general malaise and weakness. The boy's friends said he had been carrying unusually heavy loads on his shoulders two or three days before he began to complain.

State on admission.—Patient has a feverish look; lips dry and cracked; tongue dry, furred on dorsum, and glazed at tip and edges; appetite gone; bowels constipated, motions natural in colour; some abdominal pain; heart and lungs normal. Pulse 108; respiration 28; evening temperature 102·4°. Pupils contracted and equal. Tache cérébrale brought out on abdomen and arms. Patient has tendency to delirium; never lifts his head, complains of frontal headache, cries out suddenly, the cry having a cerebral character. There are diffuse stiffness and pain in the neck, most marked on the right side. For some days the patient continued in much the same state, being generally delirious at night and quieter during the day. Bromide of potassium and opiates were given when necessary, cold lotions were applied continuously to the head, and a blister raised on the back of the neck. Temperature in the morning 101° to 102°, in the evening 103° to 103·8°; respiration normal; pulse 112 to 120, regular. From April 9th to 17th there was some improvement, the pulse and temperature being rather the normal, and the patient being quieter. The pupils were now unequal in size, the right being larger than the left. At this time the temperature rose on two successive nights to above 104°. Croton oil was effectually applied to the back of the head. The symptoms showed general improvement, though slow, till the end of April, when the temperature fell to normal, and the other symptoms disappeared. Bowels remained normal all through. Discharged on June 10th, quite well.

Remarks by Dr. SINCLAIR.—That the possibility of enteric fever was never seriously entertained will excite no surprise after a perusal of the clinical history of this case. Was it tubercular meningitis? Was it an instance of that malady which I am not alone in believing to be extremely rare—viz., acute simple idiopathic meningitis? Or was it a case of meningitis due to an obvious external cause? I must say that tubercular meningitis has never come forcibly before my mental vision in a case of this description, least of all, perhaps, in the earlier stages of its course. That the patient did not die does not by any means exclude the possibility of a tubercular origin; but the age was rather against such an explanation, because, although the disease sometimes occurs beyond the age of ten, it is much commoner before that age, and commoner still between the ages of two and five. It will be observed also that there was no prodromal stage, with its wasting of the adipose and muscular tissues, its languor, mental torpor, unstable emotions, and irritable temper. The pulse was never slow and irregular in the stage immediately succeeding the stage of invasion. The temperature at the time the patient came under observation and subsequently was nearly always too high for this explanation. The idiopathic theory seems to me untenable so long as any other agency can account for the morbid condition. We had here to deal with a previously healthy boy eleven years old. A sudden invasion, a well-marked attack of cerebral meningitis, probably an effusion of lymph, and a complete mental and physical recovery. We had a history of an unusually heavy load having been carried on the shoulders a few days before the onset of the attack; and this I am convinced gives us the solution of the difficulty. The unusual exertion caused, I believe, a determination of blood to the head, and initiated a sequence of events very similar to those which follow closely upon that vaso-motor paralysis which is apt to be induced by exposure to the direct rays of the sun or artificial heat. The recovery was complete, although slow. How much of the result was due to good nursing and careful feeding and how much to the local treatment I am not prepared to say.

CEREBRAL ABSCESS DUE TO CHRONIC SUPPURATION OF THE MIDDLE EAR; DEATH; AUTOPSY.

(Under the care of Dr. SINCLAIR.)

For the following notes we are indebted to Dr. D. J. Reid, late house-surgeon:—

J. Y——, aged twenty-two, carter, admitted on August 17th, 1883, with the following history:—The patient had a rigor three days ago and another last night. Since then he has complained of pain in his head, especially on the left side.

On admission he was so sick that he had to lie down at once. Tongue covered with a creamy fur, and the papillæ enlarged. There was no eruption on the body. His aspect was heavy; pupils natural. He had slight photophobia. Temperature 102°; pulse 144; urine acid, sp. gr. 1024, with slight albumen.

August 18th.—Temperature 103·6°; pulse 84. Ordered dry cupping to the nape of the neck; hair cut short; ice-bag to head. Ordered twenty grains of bromide of potassium every six hours. Had a rigor at 1.45 P.M., and was livid. Morning temperature 103·4°; evening, 101·6°, and at midnight 103·4°.

19th.—Temperature 101·2°; pulse 108; slept fairly well; headache gone. Evening temperature 99·8°; had a rigor at 7.35 P.M., when the temperature rose to 105°.

20th.—2 A.M., temperature 105·6°; 9 A.M., 103°; has had diarrhœa since last night; stools of a "pea-soup" character; 6 P.M., temperature 98·4°.

21st.—9 A.M., temperature 98·4°; 6 P.M., temperature 101°; bowels opened twice to-day.

22nd.—9 A.M., temperature 99·2°; 6 P.M., 100·4°; bowels opened twice; severe headache.

23rd.—Morning temperature 102°; spleen enlarged; slight cough; lungs normal. Ordered a diaphoretic mixture twice daily. Evening temperature 104·4°; bowels opened once to-day.

24th.—Morning temperature 100°; evening, 100°; rigor this forenoon.

25th.—Died this morning at 6.15.

Autopsy.—Abdomen: No peritonitis; omentum injected; intestines filled with loose dark yellow stools; considerable injection of upper half of large and lower two feet of small intestine; some enlargement of solitary glands; no ulceration; spleen large and congested; liver and kidneys normal. Thorax: Heart and lungs normal. Head: Dura mater slightly adherent posteriorly. On removing the brain a small collection of ill-smelling pus was found over the upper surface of the petrous portion of the left temporal bone, between the bone and the dura mater. There was some inflammation and very superficial softening of the temporo-sphenoidal convolutions in the immediate vicinity of the abscess. On sawing through the petrous portion of

the temporal bone the cavity of the middle ear was also found to be filled with ill-smelling pus. There was no discharge in the external auditory meatus, although the tympanic membrane was entirely wanting.

Remarks by Dr. SINCLAIR.—We had here to deal with an entirely different state of matters from that which existed in the preceding case. But I think the two cases may be profitably studied in juxtaposition. The ages of the patients were different; the first a boy, the second a young adult. The results were different; in the former recovery, in the latter death. There may be some difference of opinion as to the cause of the malady in the boy's case; there can be none in the man's. In the case now under discussion it is true the invasion was apparently sudden. But the clinical history was unfortunately very brief, and was marked by rigors and a very irregular range of temperature. The post-mortem examination showed clearly that the fatal result was due to causes which could not possibly have been averted when the patient came under treatment a week before death. The secondary abscess of the brain was beyond a doubt due to an old-standing middle-ear suppuration. To the practically indefinite possibilities for mischief of which this local affection is capable attention has been frequently drawn both by physicians and specialists. In the *Edinburgh Medical Journal*, June, 1881, I drew attention to these dangers, and cited three fatal cases in support of my argument. One died from cerebral abscess, one from pyæmia, and one from pyæmic pneumonia. Such cases appeal specially to the general practitioner, who usually sees them long before the specialist. In its early stages the treatment of suppuration of the middle ear does not usually present formidable difficulties, and should in most cases, with a very moderate amount of skill and care, be brought to a successful issue. Yet, as I ventured to say in the paper just mentioned, "Everyone who sees much of ear diseases is painfully familiar with two reasons assigned by medical men for allowing tympanic suppurations to proceed unchecked that they cannot be cured, or that they should not be cured. The former answer presumes an amount of intractability which belongs to few suppurations in otherwise healthy individuals; the latter ignores the anatomical seat of the disease."

THE GENERAL HOSPITAL, BIRMINGHAM.

CASE OF SUBSPINOUS DISLOCATION OF THE HUMERUS.

(Under the care of Mr. HASLAM.)

J. McC——, aged thirty-two, applied at the hospital, saying that he woke up in the middle of the night feeling pain in his right shoulder, and that this was due to some twist in bed. (It was afterwards ascertained that he had had a fit.) On examination there was found to be considerable pain about the shoulder on any attempt to move it, the arm was fixed with the scapula, flexed to an angle of 45°, slightly rotated inwards, and the axis of the bone was directed to a point just posterior to the glenoid fossa. On feeling for the head of the bone below the acromial end of the clavicle a distinct depression was felt with hollow tension of the anterior fibres of the deltoid. On inspection posteriorly a slight swelling was noticed just below the junction of the spine of the scapula with the acromion process, and on manipulation this was found to be due to the upper end of the humerus resting on the dorsum of the bone. No reliable measurements could be taken as he had sustained an injury to the elbow when a boy which had totally disarranged the bony prominences. Reduction was easily effected under anæsthetics by a movement of abduction, extension, and rotation outwards.

THE BRITISH OPHTHALMIC HOSPITAL AT JERUSALEM.—This hospital, which was founded in 1882 by the English branch of the Order of St. John of Jerusalem, has, during the first twelve months of its existence, relieved patients to the number of 2546. Owing to the resignation of the resident officer and the difficulty of meeting with an eligible successor, its operations were suspended during the greater portion of last year, but they have now been resumed, and the medical officer reports that the interregnum has only increased the eagerness of the people to avail themselves of his services. The limited funds at the disposal of the Committee will not permit the reception of in-patients, and subscriptions are asked for to remedy this state of affairs.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Conclusion of the Discussion on Charcot's Disease.

A SPECIAL meeting of this Society was held on Dec. 23rd, Sir Andrew Clark, President, in the chair. The meeting was prolonged till 10.45 P.M., in order to bring the discussion to a termination.

Sir ANDREW CLARK said that the discussion had elicited the information that Charcot had been misunderstood, and therefore with a view to preventing further mistakes he would briefly summarise the position which Charcot took. Arthropathies may occur independently of any specific influence from any specifl nervous disease. Further, an ordinary osteo-arthritis may occur in the course of tabes dorsalis. There were many injuries and diseases, acute and chronic, of the nerves, spinal cord, and brain, which produce arthropathies of various kinds, and amongst them was one which from its pathological appearances and the assemblage and progression of its clinical symptoms deserves and, indeed, demands a specific name, and this was Charcot's disease itself.

Mr. MACNAMARA said there was abundant evidence to show that Charcot's disease was not very uncommon, seeing that from a single London hospital Mr. Lunn had in a brief period collected five typical cases of the disease. There could be no doubt that some diseases of joints were dependent upon altered nervous influences. And the influence of the neurotic element would serve to elucidate and explain some of the mysteries which surround diseases of the joints. A joint may be regarded as an interruption in the continuity of bones; embryology clearly points out this, and histology confirms it, for the synovial membrane was a modified form of periosteum, and there were a large number of osteoblasts about the junction of the periosteum with the synovial membrane. Disease confirms the same ideas, for in chronic non-suppurative affection of joints osteophytes were met with at the junction of the synovial membrane with the bone; these outgrowths were not peculiar to chronic rheumatic anthritis, or to Charcot's disease, since they were found in all joints affected with chronic non-suppurative disease. Ununited fractures and syphilitic gumma of bone exhibited similar changes. Dry bones were extremely unreliable guides in dealing with the pathological nature of joint disease. It was more than eleven years ago since Dr. Buzzard said that chronic osteo-arthritis may also occur in locomotor ataxy. Clinically the difference between Charcot's disease and chronic rheumatic arthritis was still more marked, and detailed reference to Mr. Barker's case showed the typical differences extremely well. After some time the left knee-joint was entirely disorganised, and this fresh arthritic attack was preceded by disorders of the nervous system. The painless course and the fact that the disease never leads to ankylosis of the joint, and that in not a few cases the patient recovers, were striking, for the direct opposite obtained in chronic rheumatic arthritis. The morbid process was that of a rapidly advancing rarefying ostitis. In reply to Sir Andrew Clark, he said that he believed chronic rheumatic arthritis was almost always attended with pain, and that condensation of bone was the chief process.

Dr. BROADBENT said there was nothing in the extent of his experience which would lead him to have taken part in the debate, but the protraction of the debate would possibly allow of a few remarks. One of the most important points which was touched upon by Sir James Paget was the notion that the articular affection was a new disease. This feature, he thought, had not been rightly appreciated, for the information at hand left no room for the identification of this disease with chronic rheumatic arthritis. Sir James Paget's authority was unrivalled on the subject. It was descending to the level of mere cavil to endeavour to connect the two diseases by intermediate links, especially when those links are based on dry specimens of bones. Further, the clinical features establish a complete distinction. In the history of disease, vital processes are of far greater importance than morbid anatomy. There were at least four different ways in which joints became deformed, which give results like those seen in chronic osteo-arthritis. Under the term chronic rheumatic arthritis there came at least two distinct diseases;

that occurring in young females was perfectly distinct from the affection termed morbus coxæ senilis. Then there was the arthritic disease: the result of tabes dorsalis, and very similar results may be due to neglected chronic synovitis. What is the new morbid factor in the arthropathy of tabes dorsalis? The views which he held would coincide very much with Charcot's conclusions. Sir James had spoken of the search after the causation of the disease, implying that it was the resultant of different possible morbid processes, such as rheumatism, gout, rheumatic arthritis, syphilis, and so forth, with the view of tracing the dominant influence. But Dr. Broadbent believed that such an object was a hopeless quest, and was a research which would have no particular value. Syphilis was amongst the antecedents of tabes dorsalis, and so we might admit a remote connexion between syphilis and the disease in question. The "slipshod" treatment, the neglect of radical treatment of early syphilis, was possibly responsible for the increased frequency of such nervous diseases. He considered that the view which endeavoured to establish a relation by like causation was a very hopeful one. A derangement of nutrition of the joints may be brought about by disorder of the nervous system, which might be excited reflexly in chronic rheumatic arthritis, and directly in Charcot's disease as the result of a persistent irritative lesion of the spinal cord. If this could be established, we should have gained an important step. It was an explanation of chronic rheumatic arthritis through tabes dorsalis, and not an explanation of tabes dorsalis through chronic rheumatic arthritis. This was very much the position taken up by Dr. Ord, and he considered that the weight of evidence tended strongly in that direction. With regard to the illustration of Charcot's disease by herpes zoster, he did not see so much incongruity as Dr. Moxon did. For it must be remembered that herpes leaves cicatrices, may damage an eye, may lead to atrophy of the entire area supplied by a nerve, and so he felt that the comparison did hold good and was a fair illustration. In his grave philosophic way Mr. Hutchinson had referred to the passive influence of the nervous system, but Dr. Broadbent asked whether the explanation was in accordance with our experience. Was it true that Charcot's disease was generally found in those parts in which the anæsthesia and flinging action of the limbs were most apparent? In his experience the reverse was the case. It was not unfrequent for the ataxy to be discovered after the occurrence of these tabetic phenomena. All that he had ever seen pointed to the exactness of Professor Charcot's views. He had been sorry that Dr. Moxon in proposing a vote of thanks to Charcot should have thought fit to adopt a tone of sarcasm, not to say mockery. He would be sorry indeed to miss Dr. Moxon's presence from our meetings and periodicals, for that would be one pleasure less in life, and would be a great loss to medical science, but still he thought we should have been better spared it on that particular occasion. He considered that such a method of giving a vote of thanks compromised the Society. Dr. Moxon tried also to throw discredit on Charcot's work, and, burlesqued as the information on metallotherapy was, yet it was plain that Dr. Moxon must be in absolute ignorance of the nature of this metallotherapy and Charcot's attitude towards it. Burq had eccentric ideas no doubt on the influence of different metals on unilateral anæsthesia, but Charcot had all along adopted the attitude of a spectator, and would no more think of partaking in any extravagances than Dr. Moxon himself. No one had a stronger respect and regard for Dr. Moxon than he had.

Mr. CLEMENT LUCAS said that he differed *in toto* from the speech of Sir James Paget and those who followed him. Different stages of inflammation were very much alike at their commencement. It was at the beginning of fevers and other maladies that distinction was impossible. Many speakers seemed unable to disentangle themselves from rheumatic arthritis. Chronic joint diseases must present certain similarities. In Dr. Moxon's case of traumatic arthritis of the ex-salesman's shoulder there were outgrowths of bone on the scapula. The question of a new disease had a double answer given to it by Sir James Paget. In a general sense the disease might be regarded as a new one, but in a special sense it was a combination of other diseases. The latter was the thought was a combination of errors. It was the duty of curators to collect typical specimens, and it was possible that all specimens of Charcot's disease may have been thrown away as not typical; these considerations might explain the absence of specimens of the disease in our museums. The reference to the differences presented by syphilis in different constitutions by Sir James Paget next occupied Mr. Lucas. All diseases ran different courses in different persons, and yet they did not lose their identity. Syphilis was syphilis all the world over. He regretted that more attention had not been paid to the clinical signs of Charcot's disease. The case shown by him at the Society last year was referred to with a view of showing how peculiar the early stages and subsequent progress of Charcot's disease were, gout or rheumatism being wholly unlike it. We ought to give the credit of the discovery to M. Charcot.

Dr. MACLAGAN thought Charcot's disease was totally distinct from gout, rheumatism, and chronic osteo-arthritis. In its pathogenesis we could not divorce the disease from tabes dorsalis. Because a white leg occurred in the parturient woman we could not say that the local condition had nothing to do with the general one. The general vitality of the ligaments was lowered, and there was loss of sensibility in these structures. The healthy state of the ligaments was essential to coördinate movement. The ligaments being at fault, whilst the muscles retained a great deal of power of movement, loss of coördination resulted. The ligaments give way in the early stage just as the bones do in the later stages. There was a tendency to spontaneous fracture. The inhabitants of La Salpêtrière did not use their arms much, and so it was the lower extremities in which the joint disease occurred most frequently. The arms of a cooper were more likely to be the site of joint disease owing to the excessive use of those limbs. We owed a great deal to Charcot, and the miliary aneurysms as causes of central hæmorrhage were specially mentioned in this relation. In answer to Sir Andrew Clark, he said that he agreed almost completely with the views of Dr. Pye-Smith in believing that a new disease was impossible.

Dr. CHARLTON BASTIAN said that his own experience of Charcot's disease was limited, though he had been on the look out for it since 1868, and had seen very many cases of locomotor ataxy. He concluded, therefore, that the joint disease was not a necessary appanage of the ordinary lesions of locomotor ataxy, and this was precisely Charcot's position. He believed that when the joint disease was present there must be an extension of the ordinary pathological process either into the anterior grey matter or elsewhere. Some points seemed to have been lost sight of by Dr. Moxon and Dr. Pye-Smith. The ordinary lesions of locomotor ataxy are situate in the posterior columns of the cord, and if it be such a common disease as we have every reason to suppose it is, it is strange that the joint affection is so rare. Such considerations must tend to throw considerable doubt on the views which attribute to loss of sensibility and to spasmodic action of muscles a share in the etiology of the disease. Moreover, the joint disease frequently manifests itself at the very early stages of locomotor ataxy; at other times it comes at irregular periods of the disease. The influence of neural disturbances in the causation of simpler joint affections was well seen in certain cases of hemiplegia. A simple arthritis may come on in the limb only on the paralysed side; there was tenderness over the nerve trunks, with atrophy of muscle. Such conditions were associated with sclerosis of the lateral columns of the spinal cord, and in some cases recorded by Charcot there was extension from the sclerotic region into the contiguous grey matter, and it was to this extension or coincident changes in the nerves of the limbs that the arthritic disease was probably due. Sometimes joint changes occurred in the course of progressive muscular atrophy, and a remarkable case in which there was an unusually rapid onset was narrated. The pain, tenderness, and inflammation of the joints led to the diagnosis of rheumatic fever by the doctor in attendance. During the past two years it had been shown that the ordinary kind of symptoms of locomotor ataxy may exist without central changes, for there were only peripheral lesions to be detected. Future investigation would have to decide on the precise relation of the association, but we need not postulate the existence of special trophic nerves, for the cutting off of ordinary nerve impressions was sufficient to bring about secondary degeneration in the brain and spinal cord as well as atrophy of muscles with fatty degeneration. Perhaps one-half of the trophic lesions owed their existence to this absence of neural incitations, whilst a large proportion might be produced by unnatural influences passing along sensory nerves, these influences arising from changes in their tract or at

their roots. Cutaneous eruptions, damage of the cornea, and the peculiar atrophies described by Sir James Paget probably owned this pathology. There was no reason why sensory nerves should not transmit impressions in the opposite direction to their usual one. The joint affection may be due to disorder of the sensory nerves or nuclei; he threw this idea out as a suggestion. At present it was impossible to go further in the direction of a precise pathogenesis. The notion that it was a new disease was diametrically opposed to the conclusions of Charcot and to his own views; it was simply that the disease had not previously been recognised, for we could not doubt that the same kind of influences were at work in every period of civilisation.

Mr. HOWARD MARSH referred to the interest which Sir James Paget had introduced into the debate by his remarks on the subject of the evolution of disease. As neither Hunter, Langstaff, nor Stanley had left behind any specimen of Charcot's disease, Sir James concluded that the disease was new, and that it had arisen out of the mingling of constitutional affections like syphilis, rheumatic gout, and a special tendency to disease of the spinal cord. Stanley worked at diseases of the bones down to 1850, so that by Sir James's argument the affection must have become prevalent only within the last thirty or forty years. But the work of Paget himself extended down to at least 1865, and, as it was as unlikely that he had overlooked it as that Stanley had, we must, by this argument, hold that it was new since 1865, a conclusion more difficult to accept than that Hunter had overlooked it. The theory of recent evolution seemed untenable on three grounds. First, he could not see from what elements it had been so lately produced, for syphilis, osteo-arthritis, and nervous diseases had been mingled long before even Hunter's day. Secondly, the time less than even a single natural life, and less than even two generations —assigned by Sir James was probably too short for the evolution of a new disease presenting such remarkable features as Charcot's disease. Thirdly, in any process of evolution the original form gradually faded out and the new form took its place; but syphilis, for example, had remained unchanged for at least a hundred years. Osteo-arthritis and Charcot's disease seemed to him closely allied, not only pathologically, but even clinically, if the whole group instead of extreme cases were compared. He was aware that the argument that because two diseases could be connected by a number of intermediate links there was no essential difference between them must not be carried too far, for this was a form of argument by which it was easy to show that there was no difference between a saint and a sinner or between black and white. Still it was entitled to considerable weight when the intermediate cases were carefully selected. He had recently seen a case of disease of the hip-joint which began ten years ago as a well-marked example of osteo-arthritis, but which had very gradually acquired the characters of a typical Charcot's joint; yet the patient had no symptoms of disease of the nervous system. We were at present ignorant of the true nature of osteo-arthritis—whether, as many thought, it was a disease of nervous origin, or, as others suspected, himself among the number, a common name for several distinct affections not yet distinguished from each other; and thus we were not in a position to say how, if at all, Charcot's disease was related to it. Charcot's disease seemed, as Dr. Buzzard had remarked, to be located primarily in the bones, which underwent an active and destructive alteration. No bones that were suffering merely from deficient repair would present the features observed in these cases. Mr. Hutchinson had shown a skull and lower jaw in which, corresponding to the distribution of the fifth nerve on one side, the several bones were intensely hard, greatly thickened, and deformed by irregular nodular swellings. Such an example seemed to point to some abnormal influence of the nervous system. To the naked eye the changes of Charcot's disease somewhat resembled those found in mollities ossium, in which the bones become rarefied, brittle, soft, and easy of fracture. Somewhat similar changes were to be seen in some cases of fragilitas ossium. The origin and true nature of such diseases, including the osteitis deformans of Sir James Paget, were altogether obscure. Charcot's disease must be compared in every way with such diseases, and its own features must be carefully worked out before its true position in pathology and clinical medicine could be determined.

Dr. BARLOW asked whether, with regard to the view that Charcot's disease was indistinguishable from rheumatoid arthritis, the latter affection itself was so definite a clinical entity. Does such an association of the diseases add anything to our knowledge? Look at the different ways in which rheumatoid arthritis begins. First, in some cases it was impossible to distinguish it from senile degeneration, and senile degenerations of cartilage may be very extensive at the ends of bones and practically free from pain in old people. It could not be denied that acute rheumatism did sometimes develop rheumatoid arthritis. Heberden's nodes were sometimes associated with deposits of urates of soda in the joints, as shown recently by Dr. Dyce Duckworth; the coexistence of gout and rheumatism was spoken of by Hutchinson, but it was also a tenable hypothesis that the bony outgrowths were themselves due to gout. Dr. Barlow had seen malum coxæ senilis supervene on acute specific disease. The case of an old lady, who had a virulent attack of scarlet fever which was followed by changes in the knee and hip, was narrated. Another case had supervened on an attack of measles in a child. Gonorrhœal rheumatism was said by some not to be distinguishable anatomically from rheumatoid arthritis. He had observed two cases of spondylitis deformans in individuals aged forty; acute rheumatism in one and gonorrhœa in the other seemed to have played a part in the causation. Rheumatoid arthritis had also been shown by Dr. Ord to begin in connexion with dysmenorrhœa. Thus rheumatoid arthritis is merely an anatomical term, meaning a condition brought about by a great many processes. The life history was the thing which must come into play in judging of the nature of a morbid process. He had observed affections of joints in cases of hemiplegia, progressive muscular atrophy, and infantile palsy. In a case of old-standing infantile palsy the hip-joint may show decided resemblances to tabetic arthropathy in the mobility of the joint, the looseness of the ligaments, and the atrophy of the upper end of the femur. Sometimes, in the *acute* stage of infantile palsy, he had observed swelling round about joints, associated with tenderness, redness, and heat of skin, occurring within the first two weeks of the febrile illness; the swelling was more like gout than anything else, and came within the circle of the febrile disturbance of the affection. In a case of myelitis in a young lady, which came on with the symptoms of spinal apoplexy, an effusion in the knee-joint appeared and subsided three times. Brain disease was also associated at times with similar arthritic changes. With regard to the *modus operandi*, he concurred with the views of Dr. Bastian, that much further investigation was required, but that it seemed probable that joint changes might arise not only in connexion with central but with peripheral nervous disturbances.

Dr. BERNARD O'CONNOR spoke of the pathological conditions in dry arthritis, and contrasted the changes with those of Charcot's disease. The influence of nervous lesions in the causation of arthritic changes was also discussed.

Dr. HADDEN believed that Charcot's disease was a distinct and separate malady. The clinical and pathological evidence was sufficient to establish this conclusion. As to the disease being a new one, he had considerable doubt. A description was read from Stanley's work, in which there seemed to be abundant evidence to show that the case described was one of locomotor ataxy associated with joint disease, which seemed to be fairly typical specimens of Charcot's disease. Charcot had described changes in the anterior horns of the spinal cord; the multipolar cells were atrophied in parts just above the lumbar enlargement, and in the cervical swelling in cases of disease of the knee and shoulder respectively.

Dr. BASTIAN interposed to say that he knew of these changes, but he questioned what precise relation they had to the joint disease.

Dr. HADDEN, in continuing, believed that there might be some close connexion between the changes in the cord and the arthritic disease, for there was also rapid wasting of the muscles. He postulated the view that an anterior polio-myelitis of certain sets of cells was the cause of the joint disease.

Mr. HOPKINS discussed the possible influence of traumatic elements in the causation of the bone and joint changes of locomotor ataxy; the symmetry and anæsthetic state were spoken of as evidence in favour of traumatic influences. A case was referred to in which there was effusion into the thigh and into the knee-joint, with laceration of ligaments and fracture of bones.

Sir ANDREW CLARK said that the Society was to be congratulated on the way in which the discussion had been initiated, continued, and completed. It had been a most interesting and important discussion, for more varied and distinguished visitors had never joined in a debate. It was further a pronouncement of English opinion, and communicated to the busy practitioners accurate, extensive, and important information. Moreover, he hoped that it would do justice to a distinguished foreign physician to whom we owed so much. It might be interesting at this period to pass in review the opinions of the various speakers but that this had already been so ably done by one of the medical journals (THE LANCET). Another method of studying the debate was to collect and contrast the ideas which have been evolved during the discussion. Despite the wish of Dr. Broadbent and others, Sir Andrew forbore to take further part in the discussion, averring that he considered it inconsistent with the functions of the Chair.

Mr. MORRANT BAKER said that he should not reply *seriatim* for fear of being accused of "emptying the church down to the sexton." Chronic osteo-arthritis was neither rheumatism nor gout. He considered Charcot's disease was a fairly definite disease, and characterised by the same pathological changes as chronic osteo-arthritis. It was not fair to take out-of-the-way cases. If typical specimens of the affections were taken, no real distinction could be found to exist pathologically. He did not think that Charcot's disease was an accidental combination of chronic osteo-arthritis with tabes dorsalis. It was impossible that we could expect the clinical symptoms to be the same in all cases. He referred to a case under Mr. T. Smith's care, in which the hip-joint was diseased in a manner precisely like that of Charcot's disease, but there were no symptoms whatever of tabes dorsalis. He had had the rare experience of finding Charcot's disease in cent. per cent. of the cases of locomotor ataxy which had come under his care. In Charcot's disease the small joints were affected; there might be eburnation of bone and fibrous degeneration of cartilages, so that he could not agree with Mr. Barwell. He did not concur in the belief that the disease was a new one. The differences from chronic osteo-arthritis were not so startling, and he believed that Charcot's disease had been overlooked because it was uncommon. The rare specimens might have been thrown away on Mr. Lucas's showing. With Mr. Hutchinson's view on premature senility he fully agreed. The term "rheumatic arthritis" might with advantage be discarded. Words were made to be our servants, but after they were once created they might become our masters. He would like to see invented a term which would imply "decay without repair" without ambiguity. In many of the cases the joints had not been subjected to any unnatural friction, and so he opposed the theory advanced by Dr. Moxon and others. He believed that the disease had nothing to do with syphilis. It was said by Dr. Moxon that the charm of genius was to play around the ordinary, and he considered that the speech of the author of that phrase was an admirable example of its truth. He thought with Mr. Hawkins that injury had something to do with the causation of Charcot's disease, and fractures of bones in tabetic patients. It was not for him to dogmatise, but he still maintained that Charcot's disease was most probably an osteo-arthritis occurring in tabes dorsalis.

THE BRITISH GYNÆCOLOGICAL SOCIETY.

WE are asked by one of the Secretaries of this new Society, Dr. Fancourt Barnes, to publish the following:—

At a meeting held on Dec. 27th, at the rooms of the Medical Society of London, under the Presidency of Dr. Routh, the British Gynæcological Society was instituted after some discussion. The following is a list of the officers who were unanimously elected by the meeting:—Honorary President: Dr. Robert Barnes. President: Dr. A. Meadows. Vice-Presidents: Drs. Aveling, Granville Bantock, Routh, Thomas Smith, Mr. Lawson Tait (Birmingham), Professor A. R. Simpson (Edinburgh). Council: Dr. Sinclair Coghill (Treasurer), Dr. Grigg, Messrs. T. Nunn, Noble Smith, Alfred Rees, Drs. Walter and Lloyd Roberts (Manchester), Purefoy (Dublin), Mr. Paul Swain (Plymouth), Drs. Matthew Dunbar, A. Sheen (Cardiff), T. More Madden (Dublin), John Wallace (Liverpool), John Thorburn (Manchester), with others to be added at the first general meeting. Treasurer: Dr. A. W. Edis. Hon. Secretaries: Drs. Heywood Smith and Fancourt Barnes. The first meeting of the Society will be held in April.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Dec. 18th, 1884, Mr. W. A. Garrard, President, in the chair.

Dr. KEELING introduced a patient whose Scapula had been removed nearly two years before for a Tumour involving the Bone and surrounding Muscles. There had been no return of the disease and the arm was a fairly useful one.

Dr. KEELING also showed a youth whose Left Arm had been nearly torn off and his Skull Fractured by a machinery accident. After necrosis of two inches and a half of the shaft of the humerus the ends of the bone had been tied together with wire, and splints applied. Complete recovery has taken place, the patient being now able to work at his trade as usual.

Dr. KEELING exhibited a woman in whom one half of the Scalp had been torn off in consequence of her hair being caught by a revolving machine band. The complete healing of the raw surface had been much aided by repeated skin-grafting.

Dr. DYSON exhibited a patient with Aortic Disease. His age was forty-five, and he was a brewer's drayman. The interest of the case consisted of a loud high-pitched musical diastolic murmur, the maximum of intensity being over the lower part of the sternum; the murmur was audible all over the front of the chest and in the back, also in the large arteries. There was also a systolic aortic murmur. A thrill of the same distribution as the murmur was also present. Signs of the above commenced last Easter, but it was not until Dec. 1st that the patient left off working. On that day he had a sharp anginal attack.—Remarks were made by the President, Dr. Banham, Mr. Barber, Dr. Porter, Dr. Keeling, and Mr. Baldwin.

Dr. DYSON showed a Heart from a man aged twenty-five. History of rheumatic fever many years back, but only subjective symptoms of heart disease for four years. The heart, which weighed nearly two pounds, showed signs of pericarditis, dilatation, and hypertrophy of the left auricle and left ventricle, disease of the aorta and aortic valves, also well-marked mitral stenosis. The prominent symptoms and physical signs during life pointed to aortic incompetency. A mitral murmur was present but not well defined. The kidney also was shown; it was large and cirrhosed. The liver and spleen were immense. Convallaria was administered in this case, and seemed to act quite as well as digitalis. The urine was albuminous.—Dr. Porter and Mr. James made observations.

Dr. BANHAM introduced a patient whom he considered was suffering from Tumour of the Brain. There was partial hemiplegia with some anæsthesia of the left side, slight paresis of the right side, deafness of the left ear, nystagmus of the left eye, and atrophy of both optic discs, especially of the left. Headache and vertigo were also occasional symptoms. The defect of sight and hearing had been progressing for the last four years, but no paralysis beyond slight weakness of the left arm appeared until January last, when one night he was suddenly seized with cramps and rigidity of the limbs, followed in a few hours by left hemiplegia. The affection of the right side had slowly developed since. The history of the patient and the negative results following specific treatment were entirely opposed to the hypothesis of the syphilitic nature of the disease, and Dr. Banham inclined to the opinion that there was a tumour of the pons Varolii, implicating also the cerebellar peduncles, and that the sudden augmentation of his symptoms in January last was due to hæmorrhage in connexion therewith.

Dr. BANHAM also gave brief notes of a case of Urticaria, occurring in an intelligent woman of twenty-five years of age, which had recurred almost daily for two years past, and which had been accompanied frequently with dysphagia to such a degree that when she sat down to a meal swallowing was often found impossible, and the attempt induced such serious attacks of choking as greatly to alarm those about her. The patient had never given any indications of hysteria. He saw this patient for the first time three weeks ago, gave her careful directions in regard to diet and the regulation of the bowels, and ordered her a mixture of bismuth and nux vomica, to be taken before meals. Within

a day or two the attacks of urticaria subsided as well as the dysphagia. He thought it not improbable that the difficulty of swallowing had arisen from the mucous membrane of the throat being affected in a manner similar to that of the skin.—Dr. Keeling and Mr. Barber made remarks.

Mr. SIMEON SNELL exhibited a baby with Nævus at the Inner and Upper Angle of the Orbit, under process of cure by electrolysis; and showed also Priestley Smith's Model for Demonstrating the Horizontal Movements of the Eyes.

Mr. RECKLESS exhibited the specimen of an Ovum and its Decidual Membranes, of about eight weeks' growth, removed from a woman aged forty-one, the subject of old-standing retroflexion of the uterus. A peculiarity was that the ovum appeared to have been arrested at the entrance into the uterus, and developed in the corresponding corner; and that the placental portion formed a complete coat of the uterine cavity. A further point of interest was the vexed question of the possibility of pregnancy in a well-marked retroflexed uterus.

Reviews and Notices of Books.

A Treatise on the Continued Fevers of Great Britain. By CHARLES MURCHISON, M.D., LL.D., F.R.S. Third Edition. Edited by W. CAYLEY, M.D., F.R.C.P. London: Longmans, Green, and Co. 1884.

IT is now twenty-two years since the first edition of this work appeared—a work that speedily obtained a world-wide recognition, and established for its lamented author a reputation which was fully deserved. In 1873 he published a second edition, much amplified and extended; and now, after the lapse of another period of eleven years, appears this third edition, the preparation of which has been fittingly placed in the hands of his former colleague, the present Senior Physician to the London Fever Hospital, where Murchison gained so much of his experience on the subject. Much praise is due to Dr. Cayley for the judicious manner in which he has exercised his function as editor. He has not excised more than was absolutely necessary, and has been almost too sparing of additions; but, as he states in his preface, he "believed that he could best meet the wishes of the medical profession, as well as of Dr. Murchison's representatives, by making as few alterations as possible." In taking this course the editor has left the work, so far as its method and all its important details are concerned, practically as Murchison wrote it; and where additions have been made, they concern in the main the few points which have of late years received much attention. In one direction, that of the dependence of specific fevers upon the presence of micro-organisms, there has been less said than might have been thought necessary; yet it is evident that in Dr. Cayley's opinion the facts at present advanced on this head with regard to typhus and typhoid fevers do not warrant too firm an adhesion. As regards relapsing fever, the evidence is more precise; and Obermeier's discovery of the spirillum was made in the same year (1873) that the previous edition of Murchison's works was published. The description of this micro-organism, and the later investigations of Vandyke Carter and Koch, form therefore a distinct and necessary addition to the section dealing with the pathology of this disease. Seeing that this discovery was one of the first to be substantiated of the actual relation between a specific micro-organism and a disease, one is able to form some slight idea of the remarkable advances made in bacterial pathology within the past decade. In typhus and in typhoid fevers the evidence of specific microzymes is as yet very inadequate. Dr. Heneage Gibbes, who contributes to this volume an account of the typhoid micro-organisms, confesses that he has been unable to find any clear points of distinction between putrefactive bacteria and the so-called bacillus of typhoid (Eberth). He gives illustrations of these micro-organisms, but believes their specific function will be ultimately disproved. Moreover, he has found that they are very variable in number and distribution in the organs of typhoid fever cases. In another part of the work, Dr. Cayley, after speaking of the apparent necessity for putrefaction to take place in typhoid stools before these are rendered contagious, hints not obscurely as to the possibility of a conversion of putrefactive into pathogenic bacteria. A few quotations will best serve to illustrate his view. Thus, on p. 12, where Dr. Murchison speaks of the particulate theory of contagion and the *de novo* origin of fevers, the editor adds:

"Since this statement of Dr. Murchison's views on the nature of contagion the discovery of the microbes of relapsing fever, anthrax, fowl cholera, hog typhoid, and probably those of malaria, tubercle, and other specific diseases, together with the results of inoculation and cultivation experiments, has afforded fresh support to the notion that contagious fevers are due to parasitic organisms, and this must now be regarded as, in all probability, the correct view of their nature. But this view by no means disproves the possibility of their arising *de novo*, apart from the theory of spontaneous generation, which few would be inclined to accept. For the researches of Pasteur and others have shown that the properties of these organisms may be modified in an extraordinary degree by placing them under different conditions; hence it is quite conceivable that the germs of a disease like typhoid or typhus fever might under ordinary circumstances be harmless, and only acquire virulent properties when under the influence of pent-up stagnating sewage, or overcrowding and imperfect ventilation, in the same manner as the bacillus of anthrax may be rendered more or less virulent by being cultivated with the access of more or less oxygen."

Again, speaking of the typhoid poison being produced by decomposing material, Dr. Cayley writes—

"Putrefactive decomposition is, however, always accompanied, and most probably occasioned by, the rapid development of micro-organisms, and as there are strong grounds for regarding the poison of enteric fever to be constituted by one of those organisms, it would seem highly probable that the putrefactive change is one of the conditions necessary for their development from the germs contained in the stools of cases of enteric fever."—p. 487.

These passages suffice to show the direction in which Dr. Cayley thinks we ought to seek an explanation of the apparent *de novo* origin of these fevers, as well as to link the now widely accepted germ theory with the facts of actual practical experience of the mode in which contagion may occur. Whether the views are such as will commend themselves to those who doubt the connexion here hinted at between putrefactive and pathogenic organisms we shall not attempt to decide.

Except in the particular of the spirillum, there has been little to add to the chapters of the work dealing with typhus and relapsing fevers. From the latter disease Great Britain has for several years past been almost free; and as to the former, the cases are now reckoned by tens where they used to occur in thousands. To be sure there are a few cities in this country where typhus still prevails to an unenviable extent; but in others, and notably in the metropolis, the fever is one which has remarkably diminished. So that of the three great "continued fevers" of Great Britain, of which this treatise affords so exhaustive a study, there is practically but one which still constantly confronts the practitioner. The editor finds, too, that most advances have been made in the knowledge of symptoms and lesions in this fever, and has thoroughly brought the work up to date. The most copious addition is that dealing with the antipyretic treatment (p. 656, *et seq.*), where the methods and results of cold bathing are clearly and concisely stated with illustrative cases, and a like discussion of recent antipyretic remedies—notably kairin—is introduced. Thus, judiciously edited, the work retains all the characteristics which Murchison impressed upon it;

and those who have not yet perused it may well turn to this edition without fear of missing any of the wide and scholarly erudition, the careful and exhaustive descriptions of clinical, pathological, and etiological facts which served to give it from the first an unrivalled place in our literature, a position which it is likely to retain. The time may come, if the sanitarian is to be believed, when the matters treated of in this volume will have little more than historical interest, like the Plague or the Black Death. Such a consummation is, however, very remote, and many generations of practitioners will be led to seek in this treatise for the knowledge which will enable them to deal with disease that may daily confront them.

A Text-book of Human Physiology, including Histology and Microscopical Anatomy. By Dr. L. LANDOIS, Professor of Physiology in the University of Greifswald. Translated from the Fourth German Edition, with Additions, by WILLIAM STIRLING, M.D., Sc.D. Vol. I., pp. 514, with numerous Illustrations. London: Charles Griffin and Co. 1885.

THIS work, which enjoys high repute in Germany, is admirably adapted for the practitioner; whilst giving an excellent summary of the present state of the science of physiology, the author never forgets the practical side of his subject, and the advantages which the treatise offers in this respect are so great that notwithstanding it is one of the largest text-books on physiology, being exceeded only, we think, by Longet's work, and perhaps by the new edition of Funke, which threatens to appear in three huge volumes, it has yet passed through four large editions in the same number of years. It has been translated by one who is well known for the scientific work he has accomplished, and who is in all respects competent for the very serious task he has undertaken. Dr. Stirling has materially added to the value of the work by inserting a very considerable number of illustrations, and by introducing in brackets many facts which render the subject more intelligible, and which have either been overlooked by the author, or have been made out since the German edition was printed. As examples of this, we may instance the account of the oncograph, under the head of the spleen; of Meade Smith's method of making an intestinal fistula; of the structure of Brunner and Peyer's glands, and of the solitary follicles; of the fluids contained in serous sacs; of Hammarsten's theory of the coagulation of the blood; of Luciani's experiments on the cardiac pulsations; of the nature of a cardiac contraction, and many others.

The plan adopted by Landois may be illustrated by a short account of the mode in which he treats the important subject of respiration. He commences by a brief account of the histology of the bronchi and lungs, to which, as in so many other places, extension and important additions are made by Stirling, comprising the observations of Débove, Frasch, Hamilton, Klein, and of Stirling himself, on the air-cells and on the pleura, with two instructive and original woodcuts. Then follow in succession the mechanism of respiration; an account of the quantity of gases respired, and the circumstances modifying the vital capacity; the number of respirations and the conditions influencing them; the time occupied by the respiratory movements, to which Stirling adds a figure with description of Marey's stethopneumograph; the pathological variations of the respiratory movements, which is a valuable section, treating of dyspnœa, the Cheyne-Stokes' phenomenon, and Harrison's [illegible]; a general view of the respiratory muscles with their nerve-supply; the action of the individual respiratory muscles; the relative dimensions of the chest, so important from a physician's point of view, with the pathological variations of the percussion sounds; the normal respiratory sounds, with their pathological variations; the pressure in the air-passages during respiration; peculiarly modified respiratory movements, as coughing, sneezing, and the like; the chemistry of respiration, including the composition of the air, the daily quantity of gases exchanged and the conditions modifying the gaseous exchange, the diffusion of gases within the lungs, the dissociation of gases; cutaneous respiration; internal respiration; respiration in a closed space; dyspnœa and asphyxia; respiration of foreign gases; effects of accidental impurities in the air; ventilation of rooms; formation of mucus in the respiratory passages and the characters of pathologically modified sputa, which is illustrated by a good woodcut showing the various objects found in sputum; the action of the atmospheric pressure; the section ending with a brief comparative and historical notice. This enumeration will suffice, we think, to show the exhaustive and eminently practical manner in which the subject of respiration is treated, and, to avoid confusion, we have omitted any reference to the very numerous points which are elucidated by a line or two, and sometimes by a whole paragraph, from the pen of the translator. With this, and the numerous other text-books on physiology at his command, no student should, we think, fail in his examination on this subject.

The Medical Student's Manual of Chemistry. By R. A. WITTHAUS, A.M., M.D., Professor of Chemistry and Toxicology in the University of Buffalo, &c. London: Sampson Low and Co. 1884.

DR. WITTHAUS has given to the medical profession a book which has long been wanted, a simple manual of chemistry, in which matters important to medical science are kept systematically in the foreground. The teacher, and still more the examiner, are apt to forget that chemistry is but a small part of the work of the medical student. It is impossible to overrate the importance of that part, but it cannot and ought not to be a very large part. To demand from the student of medicine a knowledge of all departments of chemistry is unreasonable, and tends naturally to induce flimsiness in study. A good deal of general knowledge is of course essential to the comprehension of the laws of the science, and we are by no means anxious that the student shall attempt the impossible task of learning the applications of a science the principles of which he does not understand. But, on the other hand, he is often compelled by the exigencies of the examination to "get up" a great deal that has no bearing at all on the future work of his life, and is quite unnecessary for the illustration of chemical theory. What possible good is there in compelling a medical student to learn the details of manufacturing chemistry? Is it likely that he will wish to manufacture carbonate of soda or to smelt copper ores, and, if he does, will he ever attain sufficient knowledge from any hospital course? His time at the hospital is very precious, and at present it happens that so much of it is wasted by purely irrelevant studies that he is seldom able to study properly the actual bearings of science on his own profession.

Dr. Witthaus has made a praiseworthy attempt to supply a sensible course of instruction for students of medicine, and we think that, on the whole, he has succeeded. He has cut out all, or nearly all, that he could from the time-honoured course. His descriptions of manufacturing processes are brief and confined almost entirely to general principles, and he has reduced to a minimum the history of many elements—silicon, for example—which have no importance in medical science. On the other hand, the space so gained has been filled with details of practical value to the physician. Toxicology is interwoven with the text, and a good deal of pharmaceutical and physiological chemistry as well. Thus, many pages are given to arsenic, phosphorus, mercury, and in each case methods of special analysis and an account of officinal preparations are given.

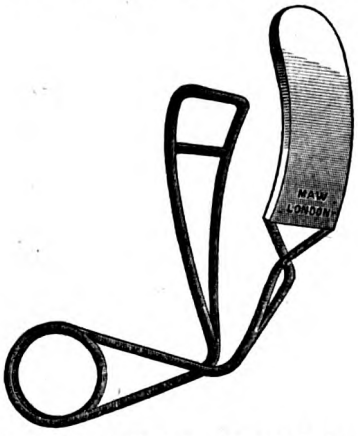
The arrangement of the elements is peculiar, and we doubt whether it is in all cases convenient. The greatest novelty is the inclusion of carbon and the so-called organic chemistry in the systematic orders of classification. About one-half the book is really given to organic chemistry, but it comes in the middle of the book after the non-metals, among which arsenic and antimony are included, and before the metals. Of course, no classification can be perfect, but this appears, on the whole, to be the best. The carbon or organic portion of the book is very good, although by no means beyond criticism. It was, for example, wise to arrange the series according to the hydrocarbon type, starting from the paraffins, but unwise to adopt the old-fashioned name of hydride for the paraffins. Schorlemmer has shown that marsh gas is no more entitled to the name of methyl-hydride than to that of methylene-hydride, or methenyl-hydride. The convenient name of methane suggested by Hofmann is now generally adopted.

We have little wish to point out errors or omissions in so good a book, as most of them are certain to disappear in the next addition. We may, however, venture to remind the author that the isolation and liquefaction of ozone, the chromic acid test for peroxide of hydrogen, the dissociation of iodine, and the use of the endiometer in analysis are matters too important to be omitted. We must notice, too, a grave error on page 174, line 5, where 180 parts of glucose are represented as yielding 44 instead of 88 parts of carbonic acid. There are, indeed, a good many inaccuracies which must be corrected if the book is to take permanent root as a text-book.

New Inventions.

NEW SELF-ADJUSTING TONGUE-DEPRESSOR.

THE engravings illustrate the construction and application of the tongue depressor. The instrument is self-adjusting, and when placed in position the operator can use both hands for any manipulation. It consists of two metallic plates in combination with a wire recoil spring. The larger or tongue plate is polished on the upper surface, and this assists in the illumination of the mouth; and on the under side it is roughened, to prevent it slipping forward



on the tongue. The smaller, or submental plate, is curved to fit easily and securely under the chin behind the maxillary symphysis. The wire spring occupies very little space, and is bent downwards so as to be out of the way of the surgeon. The blades can be easily opened, and to assist their expansion a loop of wire is fixed on each side of the spring to support the thumb and finger.[1] The instrument can be employed for depressing the tongue in any position, and therefore it will be found serviceable in minor operations about the mouth, and also in rhinoscopic and laryngoscopic examinations. The submental pressure is especially useful in patients who are intolerant of oral instruments, and this method of fixing the tongue often appears to reduce the reflex irritability of the parts. The tongue

depressor is very neatly made by Messrs. Maw, Son, and Thompson in three convenient sizes, and can be obtained from that firm at a very moderate price.

J. WARD COUSINS, M.D. Lond., F.R.C.S.,
Surgeon to the Royal Portsmouth Hospital.

[1] These wire loops are not shown in the engraving.

COTTAGE HOSPITAL CONSTRUCTION.

To the Editor of THE LANCET.

SIR,—My attention has been called lately to several new cottage hospitals which have been erected within the last few years, and which have been designed upon the pavilion principle. In the second edition of my book on Cottage Hospitals I published a plan of a model hospital for fifty beds, constructed upon this plan, but I omitted to caution the inexperienced that the pavilion system is too costly and extended for hospitals having less than fifty beds. In several of the more recent cottage hospitals the extravagance of the pavilion system for institutions with less than fifty beds is demonstrated. I have just received the particulars and conditions of two new hospitals, one at Newbury and the other elsewhere, which have been thrown open to competition, and this has induced me to ask you to be good enough to call attention to the facts here stated, and to allow me to suggest an alternative plan, based upon an exceptional experience, combined with a careful consideration of the faults apparent in several of the more recently constructed cottage hospitals.

Briefly, the plan which seems to me to be preferable to the pavilion system for small cottage hospitals is one designed upon the straight model. This will enable all the wards to be placed upon the ground-floor, with perfect cross ventilation. The matron's and nurses' rooms and the bath and operation rooms will also be provided on the same floor. Upstairs there will be the kitchens, with sleeping accommodation for the servants and staff. A lift communicating with the kitchens and ground floor should be provided. To secure the complete isolation of the kitchens when necessary, and to avoid many evils which might otherwise arise, a special staircase should connect the outside and back portion of the premises with the kitchen, by which access could always be obtained to the latter without entering the hospital. This plan also affords the widest scope for future extensions, should such be necessary at any time. I have made a calculation from which it appears that a hospital, with from eight to twelve beds, constructed upon this principle, may be built at two-thirds of the cost of one with the same number of beds constructed upon the pavilion plan, which is now so popular. I would send you a plan of my new design, but I fear you would hardly be able to find space for it in your correspondence column.

I am, Sir, yours truly,
HENRY C. BURDETT.

Gloucester-road, Regent's-park, N.W., Dec. 30th, 1884.

THE LANCET.

LONDON: SATURDAY, JANUARY 3, 1885.

WE trust the year 1885—though opening in somewhat anxious circumstances will prove a happy one for the nation and the profession. In many respects it is likely to be at least an interesting one to the profession, both in educational and in scientific matters. It is obvious that the "medical authorities"—to use the language of the Medical Act—in the different divisions of the kingdom are behaving as if a new departure were being taken and a new lease of privilege granted to them. The undertaking of the Scotch and English corporations to forego their right of granting their lowest diploma, *singly*, cannot fail to be followed before very long by similar action on the part of the Irish corporations. This welding of the licensing authority in each division of the kingdom, though not brought about in the way we had desired, and by no means so thorough as we could wish, ought to be followed by consequences of great moment to the profession. The competition between individual licensing corporations in each division of the kingdom will cease. Unfortunately, competition between united corporations in one part of the kingdom and united corporations in another part will continue, as well as a certain tendency to vulgar competition between universities granting degrees and corporations granting diplomas. But we must be thankful for small mercies till the House of Commons shows itself capable of legislation worthy of the name. So we shall charitably assume that, with a consolidation of the examining boards and an apparent reduction in the number of competing "interests," examinations will be really improved in regard to fairness as well as severity, and that medical education will gain in thoroughness. We may venture to hope that such a change in the examining bodies will have the effect of lessening the rush into the profession—the more so as, Sir LYON PLAYFAIR notwithstanding, the supply of the profession already exceeds its "waste" by several hundreds a year. There is one other "consummation devoutly to be wished"—namely, that the consolidated and strengthened bodies will have the consciousness of a little more strength to discharge the censorial and judicial functions which they owe to their members and to the profession at large. Such functions are fundamental and essential. The idea of Bodies that should license and authorise without controlling, or in case of need censuring, has no reasonableness either from the common-sense point of view or in the light of the history and traditions of the profession. The abeyance of censorial functions, however, is obvious, and is as painful as it is obvious. Every week members of some one or other of our great medical corporations are guilty of conduct which outrages the traditions of the profession, and is practically fraudulent as regards the public. But action is seldom taken by the bodies whose diplomas are thus dishonoured; and the public suffers. It is surely not too much to hope that the Corporations acting together will feel more strength and disposition to uphold professional morals and conduct. It will rarely be necessary to proceed to extremities. Many a man goes wrong, loses the respect of his professional brethren, and perhaps incurs their contempt, who might have been saved and kept in honourable and professional ways by a timely and kindly word from the censors of his College. Human nature is weak, and in the early days of professional anxiety and impecuniosity it sometimes needs a word of advice, and even remonstrance. Such a word is now scarcely ever spoken by the "medical authorities." For want of it a man often takes to courses which involve his removal from the Register. With the Conjoint arrangements of 1885 we hope for better things—not only for better education and better examinations, but higher professional spirit and conduct.

In scientific respects we enter hopefully upon the new year. There are many "worlds" of disease yet to conquer, requiring for their conquest not only the researches of the chemist and the physiologist, but the sound, steady, and sustained observations of the practitioner. There is no excuse now for any practitioner not contributing something to the great and ever-accumulating sum of medical knowledge, and still less for his not making daily additions to his own stock of practical and scientific data. The best thoughts of the best minds are our common property in these happy days of professional and scientific journalism. The opening year is full of promise. But, according to our forecast, it is full of duty. Medical problems of vast interest to mankind are pressing for solution. New remedies claim attention. New methods of treatment are replacing old ones. Even "new diseases" are spoken of by such experienced and keen observers as Sir JAMES PAGET. And old diseases, over which we had fondly hoped that Science had asserted its control, still display their ancient virulence. We have great battles yet to fight, not only with disease, but with popular ignorance and, alas! with cultivated ignorance.

LAST week we published a brief and general statement of the answer given by the Council of the Royal College of Surgeons on the 19th ult. to the recommendations of the Association of Fellows. The exigencies of space required a statement so concise that we were prevented from recording the various limitations, qualifications, and excuses which were made use of by the Council in accepting, modifying, or rejecting the recommendations of the Association of Fellows. These limitations, qualifications, and excuses do, however, form the most interesting portions of the Report of the Committee of the Council that was appointed to consider the recommendations. If the result arrived at by the Council be tried by an arithmetical test, it may be pronounced tolerably satisfactory, inasmuch as the Council has accepted, with or without alteration, *nine* recommendations, and rejected only *seven*. With this balance of two recommendations in its favour, some may think the Association of Fellows should felicitate itself and be thankful. Unfortunately, others may think that political problems cannot be solved in this simple manner. Quality as well as quantity has to be considered; and if the answer of the Council be looked at in this light, it is scarcely an exaggeration to say that the less important recommendations of the Association of Fellows have been accepted, while the more important

have been rejected. Indeed, the result might be formulated thus: *The less important the recommendation the more perfect the acquiescence of the Council therein; the more important the recommendation the more complete its disapproval.* An illustration or two will establish the general truth of this proposition.

The Association of Fellows recommended what had previously been adopted at the general meeting of Fellows and Members held at the College last March—namely, that there shall be an annual meeting of Fellows and Members at which the Annual Report of the Council shall be *presented, discussed, and, if approved, adopted.* The Council has adopted the minor part of this recommendation, but rejects the graver. The meeting may be held and the report may be presented, but it shall not be discussed. Surely this is solemn trifling! An annual meeting might have been held any time during the last fifty years; no alteration in any Charter or Bye-law is needed for holding it, as such meeting will be held under Section XVIII. of the existing Bye-laws, which was adopted fifty-three years ago, and, curiously enough, adopted expressly to prevent such meetings. And as to the Report of the Council, nothing will be gained by mere presentation: it is already *presented* every year in the College Calendar, under the title, "Secretary's Report." Again, the Association of Fellows recommended that on the receipt of a requisition signed by thirty Fellows or Members, the President shall convene a meeting of Fellows and Members. The Council falls back upon one of its notorious Resolutions, and is willing that a meeting may be held on requisition, "*provided that the objects of such meeting be approved by the Council.*" Lastly, of the recommendations accepted by the Council, the Association suggested that the Minutes of each meeting of the Council shall be suspended in the hall of the College for the inspection of Fellows and Members. Here, too, in affecting to accept the recommendation the Council inserts a condition which stultifies the concession. Only the "confirmed" Minutes are to be so suspended; in other words, those Fellows and Members who take an interest in what the Council does may from time to time know what it *has done*, not what it is doing or going to do. The Fellows must indeed be "coy and hard to please" if they be not content with being told in the middle of October what their representatives in the Council did in the middle of July or August. In any case, we cannot too highly extol the courtesy and grace of the Council in allowing the Members of the College ever to have an inkling of what has been done.

Thus it is with some of the recommendations which the Council has accepted. The conduct of the Council is, however, still more remarkable in respect to the recommendations it has rejected. Among the more important of these recommendations of the Association of Fellows are—(1) That not more than one-half of the members of the Court of Examiners shall have seats in the Council; (2) that the President of the College shall be elected annually by the Fellows; and (3) that no alteration in the constitution or relations of the College shall be made without the consent of the Fellows and Members convened to discuss such alteration. To anyone outside the Council these recommendations may seem not only reasonable and just, but directly conducive to the dignity, prosperity, and permanence of the College. But within the Council another opinion prevails, and it has pronounced against alteration. Hitherto the Council has adhered to the custom of always electing the senior member of the Council to the presidential chair; and it cannot be denied that in many cases the result has been unexceptionable. Not seldom, however, the result has been the reverse of satisfactory. There are not a few persons who believe that the custom is in itself clumsy and capricious in operation, and often in its effect derogatory to the dignity of the office of president. Judged by some instances in the not very remote past, it may safely be predicted that no election made by the whole body of Fellows could possibly be less fortunate than some of the elections which the Council has made. The contention has at least plausibility that if the Fellows were to elect the President the chances would be greatly increased that the choice would fall on the fittest—fittest not only as regards personal qualities and public spirit, but fittest also as regards professional eminence and administrative capacity. The advantages likely to accrue to the College from such a free, unprejudiced, and impartial election of the President, would doubtless be as great as its promotors anticipate. But probably even these advantages are small when compared with those that would ensue if the Council were rendered more independent of the selfish and personal influences of the paid examiners *in posse* or *in esse*, who now dominate the Council; and if, further, the legislative functions now monopolised by the Council were shared with the whole of the members of the body corporate. The particulars of the very vote recorded at the last meeting of the Council against one of the recommendations of the Association of Fellows demonstrate the evils that attend a preponderance of the influence of examiners in the deliberations of the Council. By the nature of their office, examiners are personally and pecuniarily tempted to be more zealous in maintaining the *status quo* than in favouring changes that might, among other things, curtail their own privileges and emoluments. When the motion was put that the President should be elected by the Fellows, only five members of the Council voted in favour of it, while fourteen voted against it. It is noteworthy and significant that of the five who voted for it—namely, Messrs. ERICHSEN, HOLMES, and CADGE, Sir JOSEPH LISTER, and Mr. ALLINGHAM—not one is at present an examiner, and only two have ever held the office; while of the fourteen who voted against it—namely, Sir JAMES PAGET, Messrs. MARSHALL, FORSTER, SAVORY, LUND, WOOD, POWER, BRYANT, HULKE, and CROFT, Sir WILLIAM MACCORMAC, Messrs. LAWSON, HILL, and DURHAM—no less than ten are, or lately were, examiners, and three of the other four were applicants for the last vacancies in the Court of Examiners. These facts speak for themselves, and will assuredly justify the Association of Fellows in refusing to accept the latest answer of the Council as final. The other principal recommendation of the Association rejected by the Council is of still graver import—namely, that no alteration shall be made in the constitution or relations of the College without the consent of the Fellows and Members specially convened to consider such alteration. The Council, in total disregard of the political and social

feelings of the times, naïvely answers that if such alterations were subject to the approval of the Fellows and Members, the proceedings of the Council would be rendered inconclusive, and the business of the College could not be carried on. It therefore adopts the complacent opinion "that the government of the College should still be vested in the Council." It is perhaps only natural that the Council should desire to keep the management of the College entirely in its own hands; but even this anxiety will not excuse such astute politicians confounding the distinct and separate functions of legislation and government or administration. As we understand this particular recommendation of the Association of Fellows, it was not designed to take the *government* of the College out of the hands of the Council, but merely to ensure that the whole of the Members of the Corporation should participate with the Council in *legislation*, or law-making. The absurdity of the position taken by the Council becomes manifest when it is remembered that some alterations in the constitution or relations of the College cannot be made except by an Act of Parliament, and none can be effected without the sanction and approval of one of the principal Secretaries of State. Thus the matter at present stands: The Home Secretary, say, must in every case be satisfied as to the necessity and propriety of any proposed alteration; not so the eighteen thousand Members and Fellows of the College, who are commonly assumed to have some stake in the College, and are apparently the persons most intimately affected by the constitution and relations of the College. The Council, relying upon past experience, encourages the belief that the wishes of the Fellows and Members may be safely ignored, and even despised. Do the Fellows and Members themselves concur in this opinion?

WE are able to present our readers this week with the sequel of the case of cerebral tumour submitted to operation, which has excited so much interest, even beyond the limits of the profession. We believe that a carefully detailed account of the case will be furnished in due course to one of the medical societies, and we must postpone until then any discussion of the value of the line of practice here followed out. The general features of the case are, however, well-known. A young man, otherwise healthy, presented himself to Dr. HUGHES BENNETT suffering from paralysis of the left arm, frequently recurring spasms in the left side of the face and tongue and the left arm and leg, together with double optic neuritis, severe lancinating pain in the head, and obstinate vomiting. These symptoms had been gradually coming on for three years. Dr. HUGHES BENNETT inferred from this combination of symptoms the presence of a tumour close to the front of the upper part of the right fissure of Rolando, and at his request Mr. GODLEE exposed this part of the brain, cut into it, and removed as far as possible a gliomatous tumour about the size of a walnut. For a time all went well, the pain and vomiting were completely relieved, and the paralysis but slightly increased subsequently. A hernia cerebri developed and attained a considerable size, and after some few days the patient had a rigor followed by pyrexia, and died with meningitis and cerebritis spreading down from the lower edge of the wound to the base of the brain.

Unfortunately, someone who wisely concealed his identity under the signature of "F.R.S.," with more zeal than discretion, removed the discussion of this important case from the arena of science to that of the public press. In a letter to *The Times*, it was referred to as a test case of the value of vivisection, and with some assurance the gauntlet was thrown down to the opponents of this method of research. A long and on the whole unedifying rediscussion of this question has followed, which has done little more than give an opportunity to both parties to state their case, and which certainly has not advanced the position the question had previously attained. We have on many occasions expressed our opinion upon the general question of vivisection, and have nothing further to add on that point. We hold that the attempt to prove that it is essentially an immoral practice has not been successful, for man's right to turn the lower animals into means of his own advancement includes that of gaining knowledge from them, a right which is enhanced when that knowledge can be turned to direct practical use to man himself. We also believe that vivisection has been of distinct value in the advancement of physiological and pathological science, but that none the less it is a practice that should be most carefully regulated and watched, and guarded by any means which will lessen the amount of pain inflicted, and secure that the utmost care be taken in the experiments. It has been clearly shown that, so far as Great Britain is concerned, the practice of vivisection has been free from what may at all fairly be called "cruelty," and in the great majority of cases in which the experiments are painful the animal is anæsthetised. It is therefore grossly unjust on the part of those who oppose the practice always to refer to it in terms that can only apply to it as practised in some foreign laboratories, and as if "vivisection" and "torture" were equivalent terms.

It is simply impossible to deny that the precision of the diagnosis of the seat and extent of the lesion in the brain of Dr. BENNETT'S patient would have been impossible a few years ago, and is a brilliant proof of the great advance recently made in this domain of medicine. Nor is it possible to contend that this advance would have been made without recourse to vivisection. It is true that clinical data taught the same lessons as Dr. FERRIER'S experiments, but the point to be borne in mind is that Dr. FERRIER, unaided, was able in a few months to establish facts that would have taken years and generations of observers in all countries to determine by clinical data alone. By recourse to the experimental method our knowledge was obtained with a rapidity and a certainty that was impossible by other means. Undoubtedly Nature is incessantly performing experiments for us, and it is well when we can discern them; but her experiments lack the concentration and very often the precision of those performed in a laboratory, while they are in many instances witnessed by those unable to discern or appreciate the truths they teach. Hence what clinical experience did very slowly and withal imperfectly, HITZIG'S and FERRIER'S experiments did quickly and so powerfully that their lesson is now the property of every well-educated practitioner. To Dr. BENNETT must be left the task of describing the steps by which he was led to his precise diagnosis, but we can hardly think it possible that he would deny that it

was the knowledge obtained by experiment that chiefly influenced him. The clinical and surgical question raised by this case is one that must be very carefully discussed at a time when, and in an arena where, party feeling is wholly excluded, and we trust that no injudicious partisan will render this impossible by untimely action. For ourselves, we prefer to wait until we have a far more exact account of all the details of the case than has yet been made public, before entering upon a discussion of so much moment.

DURING the last few years the views of the profession generally with regard to puerperal fever have assumed a definite form. The epidemic view of its nature which had been so long and so generally received, and which by its assumptions paralysed all efforts towards the prevention if not towards the cure of the disease, have been all but universally discarded, and the septicæmic view of the nature of the disease has taken its place. So long as the origin of the disease remained a mystery, so long was every effort to prevent it powerless, while the mystery surrounding it only increased the terror in which it was held. When its origin became known and the mode in which it spread recognised, the disease was shorn of a very great portion of its terrors. Although, when once it has made its attack, it still preserves much of its fatal character, yet we know now how to destroy its source and to a great degree prevent its onslaughts. Lying-in hospitals, which have been the scenes of its ravages, can now be conducted with as much freedom from risk to their parturient inmates as when they are delivered in their own homes. This is due to two factors -- first, our increased knowledge of the etiology of the disease; second, that which naturally follows the first, our power of preventing it. This knowledge is not the result of a lucky hit, nor of work in the dark, but of careful and laborious inquiry conducted on scientific principles. The etiology of puerperal fever was first studied, then naturally followed the study of its treatment. Our present treatment of it, our power of preventing it, is the outcome of the investigations of PASTEUR, LISTER, and others. Puerperal fever is septicæmia—the result of infection of the wounds made in the parturient canal during labour. The uterus immediately after natural labour is aseptic, for it is a fresh surface which has not been exposed to infected air. The vagina, however, is not aseptic, but there are reasons for believing that the discharges in the genital passages, although capable of infecting others, do not infect the person who generates them; in other words, there is no such thing as self-infection in normal labour and lying-in. On the other hand, there is much evidence to show that infection is caused not only by the examining fingers and instruments, but also by the atmosphere. In favour of this view is the frequency of infection in primiparæ, for in them there are usually deep tears of the vaginal orifice and perineum, and consequently larger surfaces capable of receiving infection exposed to the air; while in multiparæ such surfaces are smaller and fever is less frequent. The prevention of puerperal fever resolves itself into the prevention of infection of the raw surfaces in and about the vagina; and this is done by the use of antiseptics, so as to disinfect the attendants and also the vagina. Soon after the use of antiseptics was introduced into surgery they were employed also in midwifery, and attempts were made to carry out LISTER's practice in its entirety. Baths, the spray, vaginal and uterine injections, were had recourse to, and with good results. Such a practice, however, is not only not desirable, but in many cases is impossible. The spray and baths have therefore been discarded. The uterine douche has been found not to be free from danger, and it also has been abandoned, except under special circumstances, when it may prove of the greatest use. On the other hand, vaginal injections have been, and are, still largely used in cases of normal labour. With their use better results have been obtained than without them. Objections have been made to their regular employment, but these rest chiefly on theoretical grounds. It has been said that it is not possible to disinfect the genital passages by these means, but the fact remains that foul decomposing discharges can be washed away, the passages be rendered sweet, and the temperature permanently reduced in the course of a few hours from 104° to the normal, by disinfection of the uterus and vagina by irrigation. If in such cases the disinfection is not complete, yet in practice it proves sufficient and effectual to remove the patient from a state of the greatest danger to one of safety. Vaginal injections may not be universally necessary, but, in all large towns at least, they are a means of safety which should not be disregarded. The cases requiring disinfection of the uterus are of great rarity. All cases in which the discharge is offensive do not demand it; but if the discharge is offensive after the vagina has been irrigated, the uterus itself is foul, and its cavity should be washed out and disinfected. These measures should be regularly observed in all hospitals and in large towns, and in all cases in which manual or instrumental interference has been required.

Annotations.

"Ne quid nimis."

MEDICINE IN ART.

ASSUMING that Thackeray was justified in prescribing to painters and sculptors a "little more reading," with a view to enlarging their choice of subjects, may we suggest the history of the healing art as a comparatively virgin field for the exercise of their genius? It abounds in critical situations and dramatic episodes, nowhere so well told as in Puccinotti's "Storia della Medicina" (4 vols., 1850-66), a masterwork far too little known in England, and strangely ignored in the "Encyclopædia Britannica's" latest article on the subject. Take, for example, the figure of Fabrizio d'Acquapendente, who stands at the close of the mediæval and the commencement of the modern period—of what an interesting group might not that mighty demonstrator and teacher form the centre? In the anatomical amphitheatre of Padua his class has just risen for the session, carrying away with them the noble Latinity of his peroration, with its impressive insistance on "Dissectio" (anatomy), "Historia" (recorded observation), "Actio" (function), and "Utilitates" (practical ends), as the "Quadrilateral" of medicine, when in come Galileo and young Harvey, arm in arm. Now for the painter's art! The scene is a spacious hall with an exit door to the spectator's left, and an entrance door to his right, admitting a flood of radiance to illumine the sombre shadows on the side opposite. Near the entrance door

stands the anatomical table on which Acquapendente has still before him the fresh, open vein-trunks for the demonstration of their valves, and just beside the preparation lies his famous book, "De Ostiolis Venarum." Young Harvey, already a four years' student with Acquapendente in Padua, stands close to Galileo at the table, both of them facing the full light of the entrance door, Harvey aglow with curiosity, his left hand resting on the table, while with the forefinger of his right he indicates the valves that rivet both eye and mind, and recognises their heartward direction as discovered by his master. Galileo, before presenting to the Venetian Republic the telescope with which he made out the satellites of Jupiter, is handing it to his beloved Acquapendente, at the same time showing him an instrument case he has just put down on the table, containing his geometrical compass, square, and balance. With a genial confidence of look he seems to say to the anatomist—Henceforth these will be the weapons of the natural philosopher; by these will truly be known and demonstrated the things of creation as they are in themselves and in their relations, according to number, weight, and measure. Acquapendente, who dominates the centre of the picture, extends his right hand to take the telescope, and with his left on Galileo's shoulder he listens proudly to his fellow-worker, as if with the consciousness that he too, in his forty years' study and teaching of the science of the human body, has made new and pregnant discoveries on the gradual ascent from observation to experience. Among the shadows at the exit door to the left of the spectator, with his back to the illustrious triumvirate, retreats a long lean figure, with Aristotle's treatise, "De Cælo," under his arm, which he seems to hug as if in disdain of the instrument with which Galileo discovered the satellites of Jupiter. This is the rigid peripatetic, Cæsar Cremonini. Such a picture, according to Puccinotti, comprises and expresses the closing facts of mediæval science and the opening vista of the modern. Are there no contemporary Parrhasios and Zeuxis to compete for the honour of transferring it to canvas?

CARE OF THE SICK AND WOUNDED IN WAR.

THE *Illustrated Naval and Military Magazine* for December, 1884, contains two papers bearing on subjects of interest to our profession. The first is a translation, by Lieut.-Colonel Suther, of a paper on the "Principles of Sanitary Service in Mountain Warfare; by Michaelis, Principal Staff-Surgeon and Sanitary Officer of the 14th Corps at Innsbruck." The object of the paper is to bring to notice a modification of the Tyrolean Kraxe as being remarkably well adapted for the carriage of the sick and wounded in mountainous districts, where wheel or even mule carriage is impossible, and where, from the nature of the ground, a stretcher could not be used. The Tyrolese Kraxe, with its head-board and padded head-rest, has been in use for centuries for the carriage of heavy weights over the mountains, and a modification of this, of which four illustrations are given in the paper, has been successfully employed, and has been found to be well adapted for the special conditions of mountain warfare. The paper merits the study of the military authorities, and of those responsible for the care of the wounded. The second paper is entitled "Recollections of the Red Cross," by Major Burgess, late H.A.C., and gives an interesting account of the early days of the English branch of the Society. Major Burgess appears to have taken an active part in organising the arrangements in 1870 for the aid sent from England for the relief of the sick and wounded in the Franco-German war, and he tells his story in a very readable manner. But he appears disappointed with the course which the Society has since followed, describing it as "what once was, but is now only by name, the 'National' Aid Society." The present management of the Society does not satisfy Major Burgess, and the Charity Organisation Society also comes under his censure. Although we do not agree with all that is said about their shortcomings, we think the paper well worthy of perusal, recording as it does the commencement of one of the great philanthropic movements of the age, and giving full credit to those who laboured for it in the days of its early struggles and difficulties.

UNIVERSITY OF LONDON.

THE next meeting of Convocation is fixed for Tuesday next, the 6th inst., at 5 P.M. There are many questions of interest to medical graduates on the agenda paper. The most important are: that Convocation should again urge upon the Senate the desirability of holding the Preliminary Scientific Examination twice a year; that Convocation should meet three times, at least, in every year; that the Annual Committee consider and report as to whether there is a general feeling of dissatisfaction with the University on the part of the teaching bodies; and lastly, that a special committee of twenty-five members be appointed to consider the proposals lately published by the Association for Promoting the Establishment of a Teaching University for London, and to report thereon to Convocation at an early meeting. The graduates are evidently alive to the necessity of reconsidering the position of the University; but we fear that the Senate will hardly approach the question from the same standpoint. It is most important that medical graduates should not permit the present crisis to pass by without asserting their position and compelling their just demands on the executive.

THE FUNCTIONS OF THE THYROID.

THE lately awakened interest in the singular condition known as myxœdema, and especially the relation inferred between it and imperfection of the thyroid gland, following the results, observed by Kocher, of extirpation of that body, will have been further stimulated by the two lectures which the Professor Superintendent of the Brown Institution has lately given at the University of London. The method of determining the function of a gland by extirpating it and observing the effects of such removal is one which has often been practised, but is not always wholly satisfactory. Kocher's description of the "cachexia strumipriva" accords with the "myxœdema" of Dr. Ord, the "cretinoid state of adult women" of Sir W. Gull, and the results observed by Mr. Horsley in monkeys after extirpating the thyroid with perfect antiseptic precautions. Whereas such effects of thyroidectomy in man require a period of years for their evolution, in Mr. Horsley's monkeys the whole series of symptoms is passed through in a few weeks. Thus the operation is succeeded by nervous symptoms, commencing with tremors like those of paralysis agitans, followed by paresis and hebetude; a condition of oligæmia and leucocytosis; the appearance of mucin in the blood, subcutaneous tissues, and salivary glands, puffiness of the face and eyelids, and subnormal temperature, ending in a fatal issue within five or six weeks. In spite of this difference in the rapidity with which the loss of the thyroid takes effect in monkeys, the resemblance of the one set of results with that of the other is too close to be disregarded, and Mr. Horsley may be justified in his conclusion that the thyroid has a double function—partly glandular, excreting mucin; partly hæmatogenous. This may be true; and if it be so, an importance is given to mucin which is excreted in considerable quantity from epithelial surfaces which should raise it in estimation. That the retention of an excess of this material in the body should be injurious and fatal to the organism is a wholly new conception; but it is apparently based upon arguments as conclusive as many that

are employed to demonstrate the functions of other organs which are more intimately known to us than the thyroid. The Brown Professor may be congratulated on the manner in which he has initiated his term of office, and we may hope that he will signalise it by continuing to pursue inquiries which may throw light upon much that is yet obscure in physiology and pathology.

WHOLE-MEAL BREAD.

THE late exhibition of bread stuffs at Humphrey's Hall, Knightsbridge, although it was not so largely attended as was expected, has been the means of reviving attention to the subject of whole meal, so strongly advocated by the Bread Reform League and by its indefatigable honorary secretary, Miss Yates. If the chemists alone had to decide the question of the relative values of whole meal and ordinary white bread, the public would have to wait a long time before it could obtain a satisfactory reply; for on this point chemists differ more than doctors. If we interpret the opinion of the profession of medicine correctly there is a growing disposition in favour of the whole-meal bread, on practical rather than on theoretical and chemical grounds. The bread which contains all the constituents of the wheat, except the outer, insoluble, and irritating portion of the seed, seems, when the appetite for it has been obtained, to be more satisfying and digestible than the white and fashionable product which is found on most tables, of rich and poor alike. It is believed, too, that for children the whole meal is the best for sustaining growth and for building up the skeleton strongly and in perfect form. The supply of whole-meal bread is now much facilitated by the improvements that have been introduced in the decorticated or granulated flour, to which Lady John Manners has called public attention in her late paper on Wheat-meal Bread. In the decorticated whole meal the extreme outer coating of the wheat grain is, by a special process of abrading, to the perfection of which Dr. Morfit has rendered able service, cleverly removed. After the abrading process is completed the whole of the grain is reduced to a fine flour, in which there is retained all the substances that are nutritious and digestible. Considering the fact that the whole-meal bread when it is properly manufactured is easily assimilated, we are led to the conclusion that it must be more nutritious generally than other bread, in which starch predominates. But we do not wish to be dogmatic, and would prefer, before pronouncing a strong opinion, to hear what medical men from their unlimited field of observation have to say. It is for this reason we direct attention to a topic which must soon be very widely discussed amongst all sections of the community.

CREMATION IN AUSTRIA.

A BILL to legalise cremation has been introduced in the Austrian Parliament; and, as its provisions are only of a permissive character, there is good prospect of the project becoming law. Many other States are also meditating legislation on this subject, and it may therefore be advisable to see what are the principal features of this scheme. The Austrian Bill stipulates that cremation may only be practised when the authorities have given special permission, and when the deceased has expressed in writing or before witnesses the desire to be cremated. In the absence of any such declaration, the heirs, trustees, or administrators of the estate of the deceased may obtain special permission to cremate his body. In no case, however, will such authorisation be given if any doubt whatsoever exists as to the cause of death. Cremation must not take place earlier than forty-eight hours after death unless the authorities issue instructions to the contrary, or in cases of epidemic disease. Cremation must not in any way modify religious rites and ceremonies. The body may be burnt either with or without the coffin, if the sanitary authorities have no objection to the latter course. In this case, however, the coffin must be burnt subsequently. The ashes gathered and placed in urns shall be given to the relatives, or, in default, kept in rooms specially constructed for this purpose on the spot. On each urn the name of the deceased shall be inscribed; but the urns may be destroyed after a lapse of twenty years, and the ashes buried in the cemetery, unless they are claimed by the relatives.

FATAL WOUNDS OF THE HEART.

IT was with feelings of relief and satisfaction that the public and the profession learned of the respite granted by the Home Secretary to Elizabeth Gibbons, who had been convicted and sentenced to death for the alleged murder of her husband at Hayes, near Uxbridge. In our last issue we strenuously urged the propriety, nay, the necessity, of such a course, especially as the verdict of the jury seemed to have been founded mainly on facts deposed to and opinions given by the medical witnesses, facts which undoubtedly raised a presumption of murder, but which, on the other hand, did not warrant the correlative conclusion; for, as we pointed out, they were consistent with either of two other alternatives—viz., (1) several mortal wounds may be inflicted suicidally in rapid succession; and (2) no individual wound found on the body of Mr. Gibbons was so placed that it might not have been the result of accident or an attempt at self-destruction. The former proposition receives support from a remarkable case of suicide, the particulars of which have recently been published. An overworked student of University College, London, compassed his own death by shooting himself through the chest (the bullet traversing the wall of the left ventricle of the heart) and head. After the first shot "the young man walked several paces, and was steady enough to reload the pistol and take most accurate aim at the base of the brain, where the second ball was found on opening the skull." Death did not take place until twenty minutes after the heart was wounded. It must not be supposed, however, that such a sequence of events is likely to happen except in very rare instances. Dr. Kirkman, writing from Hastings, Dec. 25th, tells of a crow that continued its flight for 650 yards after being shot at, and then suddenly fell dead. At the post-mortem a No. 5 shot was discovered loose in the cavity of the left ventricle. Such a case is valuable as showing the uncertainty as to the time and mode of death from injuries to the heart, a question which has not met with due consideration at the hands of medical jurists. It is certain, as in the case of Dr. Kirkman's crow, life may cease from disturbance of the cardiac nervo-muscular dynamism, irrespective of hæmorrhage, or mechanical impediment to the movement of the auricles and ventricles from accumulation of blood in the pericardium. In the Woolwich tragedy now under investigation "the weapon entered the left breast and went in a slanting direction into the heart; the stab was half an inch in width, was a clean cut presenting the appearance of the weapon having been plunged into the girl's heart and instantly withdrawn, the blood around the wound coagulating and preventing bleeding." So runs the report of the post-mortem examination. To the latter deduction contained therein we must, with deference, demur, for it is difficult to tell with certainty clots formed during the act of dying from those of post-mortem date; and, again, it must not be forgotten that a narrow wound passing to the heart through strata of muscles and other tissues—the more so if it be oblique—is more likely to kill by bleeding into the pericardium than by external hæmorrhage. Where the

coronary arteries are wounded death quickly supervenes from the combined effects of shock, anæmia of the cardiac muscle, and pressure on the heart. When a medical man has to inquire into cases like those enumerated above, he should make a patient and complete observation of all the facts, and then explain them as well as may be by the rules of common sense, and by relevant scientific data. Unfortunately, medicine as a science is largely empirical. We cannot measure with mathematical exactness the causes and effects involved in the continuation of life; and therefore in proportion to the uncertainty of our knowledge should be the caution in our procedure. This precept is of paramount importance when the existence of a fellow creature is at stake.

ANTI-VACCINATION AND ITS CONSEQUENCES.

WHEN a man with the anti-vaccination craze has three of his unvaccinated children attacked with small-pox and loses them all, one cannot have any feeling so strong as that of pity—first for his ignorance, and then for the terrible price he has had to pay for it. To lose three children is bad enough, but to lose them for want of a simple operation which in the eye of the law is compulsory, and which according to experience would probably have saved them from both death and the disease, is a responsibility which must greatly aggravate bereavement. It is very like withholding bread from a starving child, or a life-buoy from a child struggling in the water. This is the sad case of a confectioner in Shoreditch, on one of whose three children, dead of small-pox, an inquest has been very properly held by Mr. Collier. Small-pox, we often point out, is the schoolmaster that will in the long run drive men to the beneficent operation of vaccination, and a coroner does great service who lets light into those homes where small-pox is allowed to have its own way. Mr. Charles Westwood will have to look far back in the history of his family or of the country for any accident from vaccination to be compared with the disaster that has accrued to his home from small-pox. Most men of fifty years' experience in medical practice will tell him that they have not known of a death from vaccination. It came out at the inquest that when the deadly plague overtook the unprotected children, Mr. Westwood sent, not for a medical man, but for a Mr. James Swindells, who advised hyssop, pennyroyal, marshmallow, and other herbs, and it was for this part of his conduct that he was blamed by the jury. Infatuated as it was, it was not so irrational as his neglect to have them vaccinated, for the most enlightened physician has nothing to compare with vaccination in opposing small-pox.

SEWAGE AS FOOD FOR FISHES.

SIR JOHN LAWES, whose distinguished services to agriculture and agricultural chemistry entitle his words to the most respectful hearing, suggests that it may, after all, be more profitable to throw the sewage into the sea than to apply it to land. The difficulties attendant on the latter system have so often been discussed in these columns that they need not be stated again. All the old hope of profit to be derived from sewage as a land manure has vanished, and the sanitarian has only now to consider how most cheaply to get rid of an ever present and dangerous nuisance. To the broad line of Sir John Lawes's argument no exception can be taken. Enormous quantities of fish are removed from the sea near our shores, and in them enormous quantities of phosphate of lime, potash, and nitrogen. Now, phosphate of lime exists in sea-water in very minute quantity, and yet it is as essential an article of food to fishes as to mammalia. If then, as Sir John Lawes contends, the sewage of large towns gives back to the sea enough, or more than enough, to compensate for the food material annually taken from it, it may well be that continued and even increased prosperity may accrue to the fisheries. Of course there would be no need to continue the present disgusting system of throwing the sewage in a raw state into a river used as the highway of nations. Even after defecation the sewage would still retain nearly all the nitrogen and much of the mineral constituents. In one respect, indeed, such a defecation would be a great advantage to the fishes, for it was proved in evidence before the late Royal Commission that the sewage throughout a large area of the Thames absorbs, practically, the whole of the dissolved oxygen on which the respiration of fishes depends. This evil would be diminished by defecation, but would only be cured entirely by a much greater dilution. The speculation is a very interesting and important one, but a great deal of further inquiry will be necessary before it can be adopted as a basis for action. We must know, for instance, from a consideration of oceanic currents whether the sewage thrown into the estuary of a river will remain near the shore, or be carried away to deep water. Even the sewage of London would be but a small contribution to the waters of the ocean.

SUCCESSFUL REMOVAL OF THE LOWER PORTION OF THE RECTUM FOR CANCER.

DR. NICCOLINO NIERI reports, in the *Gazzetta degli Ospitali* of Dec. 10th and 14th, the history of a case which illustrates in a marked degree the advantages of direct surgical intervention for the relief of cancer of the lower bowel. C. S——, aged sixty-one, born at Scorticata in Romagna, is of sound parentage and constitution, and the mother of eight healthy children. She first felt a sense of weight and occasional lancinating pain in the rectum last January. Defecation became frequent and painful, and blood was mingled with the evacuations. Cold hip baths and unctuous applications, prescribed in the belief that the affection was hæmorrhoidal, failed to give relief. The pain increased, and radiated into the loins and into the right and left hypochondria; the appetite lessened, digestion became impaired, defecation more difficult, and a yellowish sanious discharge issued continuously from the anus. Emaciation progressed; the increasing pain caused sleepless nights; the motions passed were thin; tympanites developed; and a tumour, due to accumulated fæcal matter, was felt in the left flank. By digital examination, Dr. Nieri ascertained the existence in the lower third of the rectum of a hard, irregularly shaped tumour, ulcerated in some parts, and almost completely surrounding the gut. Regarding it as of a cancerous nature, he advised extirpation, which was performed on the 23rd of August last, while the patient was in the lithotomy position and under the influence of bichloride of methylene. Two semicircular incisions were made, about an inch and a quarter from the margins of the anus, and extending to the rectum, which was dissected for some distance from below upwards; then with the right index finger the intestine was detached for a space of five inches and drawn down; some loops of thread passed through it, above the diseased portion, kept the gut immovable during the process of severance by the galvanic cautery. The edge of the gut was now carefully secured by sutures to the skin, a drainage-tube inserted, an antiseptic dressing applied, and the patient replaced in bed, still in a state of insensibility. The loss of blood was slight, and few vessels were tied during the operation, which lasted an hour and three-quarters. Severe symptoms of shock followed, with very rapid pulse, clammy and livid face, cold extremities, and occasional vomiting. These symptoms yielded, in about an hour, to two hypodermic injections of musk, warm frictions, hot bottles to the feet, and brandy by the mouth. Six hours after the operation

the temperature was 100° and the pulse 88. With the exception of some lumbar pain and sleeplessness, the patient passed a fairly tranquil night. Next morning the urine was drawn off by a catheter and the dressing changed; the temperature was 100·4° and the pulse 101. The bowels acted the same evening without any trouble. On Aug. 25th the temperature was 99° and the pulse 116. On changing the dressing a little pus was seen at the end of the drainage-tube. Irrigation with 3 per cent. carbolised water was repeated three times daily during the next fortnight, the temperature remaining all the time about normal, and the pulse ranging between 110 and 116. At the end of three weeks from the operation the patient might be considered as cured, the wound being healed, the urine and fæces voided naturally, and no febrile symptoms present. But a sharp attack of bronchitis, due to imprudent exposure, prevented the patient's return home until Oct. 10th, seven weeks after the operation. On examining the fundament just previously, the rectum was seen drawn up and much contracted, apparently realising Chassaignac's description of "sphincterisation," or formation of a new sphincter, which he observed after removal of cancer of the rectum with the écraseur (*écrasement linéaire*). On microscopic examination of Dr. Nieri's specimen, it exhibited the appearances of malignancy. The operator has added to the interest of his narrative by recalling a few facts connected with operations for the removal of cancer of the rectum. It was first practised, and that successfully, by Faget on June 30th, 1763. Lisfranc revived the procedure in 1826. His first three cases were successful; but of his subsequent six cases only two recovered perfectly, in one the result was uncertain, and three succumbed in periods varying from twenty-four hours to twenty-five days after the operation. Velpeau, in six similar operations, had three recoveries and three deaths; while Rizzoli is reported to have performed the operation four times, with uniformly good result. Nélaton had several deaths after it; but Czerny is credited with only one death in twenty-five operations (nine without recurrence) during the last seven years (Bellage in *Centralblatt für Chirurgie*, No. 20). Cancer of the rectum has an historical medical interest, as under it succumbed Broussais, in spite of the assiduous attentions of his illustrious contemporary, Amussat. Studying Dr. Nieri's case by the light of the discussion on malignant disease of the rectum at, and since, the Copenhagen Congress, and of the abundant information given in the fourteenth chapter of Mr. Harrison Cripps's recent monograph on Diseases of the Rectum and Anus, it is reasonable to hope for fresh surgical conquests, in well-selected cases, over one of the most terrible, and usually deemed incurable, maladies.

CONVALESCENT DINNERS.

"PENNY Dinners," "Invalid Kitchens," and "Charitable Dinners for Convalescents," represent schemes which differ more or less widely from one another in their immediate aims, but which teach us, nevertheless, very much the same truth, that plain food as it is now prepared and sold is a somewhat too expensive luxury for many who greatly need it, the labouring poor. An evil so evident compels attention. It must be met in some way, but how? Much criticism, as just as hard, has been directed from time to time against the prevailing and apparently unalterable extortion which constantly maintains the high prices of bread and meat. It is quite clear that the cost of these bare necessaries of life should be cheapened if the poor man and his family are to hold their ground amongst us. Charity directed towards this end, while it avoids the granting of free meals to the idle or able-bodied malingerer, cannot tend to pauperise those who can work and can find work by removing the stimulus to exertion. Payment of some sort accordingly should form a principle, to be applied wherever possible, in the conduct of each of the systems of relief to which we have referred. The now famous "penny dinner" has proved that such payment may be very small indeed, and yet suffice for wholesome fare if the latter be suitably chosen. The Charitable Dinners Society represents a system allied to that advocated by Lord Brabazon, and appeals to a class hardly less needy than the school children. For two years it has been assiduous in providing, by means of coffee-taverns and eating-houses, substantial and inexpensive meals for deserving poor people convalescent from illness. Convalescence alone, it should be observed, and not penury apart from disease, is the object of its care. We are told, moreover, that a daily dinner for one fortnight is the measure of relief which it commonly extends to each individual. This term will probably suffice in most cases to enable a convalescent invalid at least to undertake some part of his usual occupation. The funds of the Society, though frugally administered, have of late fallen considerably under pressure of the demand to which the laxity of trade and the state of the labour market have subjected them. An appeal for subscriptions, which we hope may be suitably acknowledged by the charitable, has consequently been issued by the hon. treasurer, Lord Chelmsford. Contributions may be sent to his residence, 5, Knaresborough-place, S.W., or to the South Kensington Branch of the London and County Banking Company. While fully acknowledging the need of having a working fund in hand for the outlying and inevitable expenses of such a Society, we hope, in the interests of a very deserving movement, that everything will be done, by imposing a light tariff on the recipients of its charity, by selection of cases treated, and by the use of the cheap and wholesome diet common in rural districts, to render it, like that in aid of school children, as far as possible self-supporting.

CHRISTMAS AT THE HOSPITALS.

THE return of Yuletide brings with it the customary excitement at the hospitals. Entertainments, presents, and good cheer, all qualified as of Christmas sort, serve to lighten the somewhat weary round of hospital work. All the hospitals have been tastefully decorated, and most have given entertainments either of a public or private kind. At University College Hospital on Monday last the friends of the institution were invited by the resident medical and nursing staff to inspect the well-decorated wards and to assist at the entertainment provided for the patients and their friends. The central table in each ward was furnished with some pretty scenes representing such stories as "John Gilpin," or illustrating life in other climes, as Russia in Winter, with skating and sledging. A grand magic-lantern exhibition, styled "Christy's Old Organ," was given by Mr. Ash. The Strolling Players held a capital concert of vocal and instrumental music. Here, as at many other hospitals, the custom prevails of making each patient a suitable and useful present. At the London Hospital the two wings of the Grocers' Company's wards, opened about five years ago by the Queen, were brilliantly illuminated on Tuesday afternoon on the occasion of the annual treat to the children in these wards of the institution. Thanks to the efforts of the sisters who conduct the nursing arrangements, aided by the money and other contributions of friends of the institution, there were two enormous Christmas trees liberally bedecked with dolls and toys of every description. A vast quantity of toys was needed to supply the large number of child patients, for the beds for children in this hospital represent the largest number set aside for that purpose in any similar institution

The sight was a pleasing one to the large company assembled, and most of the children were highly delighted with the toys and cakes. For the last eighteen years it has been the custom of the managers of the Brompton Consumption Hospital to encourage the organisation of weekly entertainments for the amusement of the patients, from the beginning of November to the middle of April. On Tuesday night there was a distribution of gifts to the inmates from two enormous Christmas trees, erected in the concert room of the new building, which were laden with presents by the Misses Heddy, of South Kensington, and other ladies. On Wednesday evening the supporters of the Hospital for Sick Children, Great Ormond-street, were invited to a Christmas tree entertainment by the Lady-Superintendent, Miss Wood. A great Christmas tree, reaching from floor to ceiling of the lofty Victoria Ward, was provided by Miss Hope, one of the sisters, and was filled with a variety of pretty and useful articles. Carols and glees were sung by the nurses. We regret to say that the funds of this excellent institution, the very first of its kind, are not in a satisfactory state.

EXFOLIATION OF THE COCHLEA WITHOUT CAUSING DEAFNESS.

OUR Vienna correspondent writes:—The loss of the cochlea, according to the ingenious researches of Helmholtz, is considered to be equivalent to the loss of hearing power. A case, however, which Professor Grüber demonstrated on Dec. 12th, at the meeting of the Society of Physicians in Vienna, would seem to go far towards refuting this view. The case occurred in a lad, aged fourteen, who had been ailing for four years, and who was admitted into Professor Gruber's wards last November. It was stated that the patient suffered from an old otorrhœa with polypus of the left ear. As the patient experienced great pain, and as paralysis of the left nervus facialis existed, Professor Grüber had no hesitation in entirely removing the polypus, and in doing so came upon the cochlea in a state of necrosis. Since the operation the patient has felt better, his pains have ceased, and the paralysis of the nervus facialis has nearly disappeared; but, strange to say, the lad's affected ear has regained its power not only of recognising sounds, but of distinguishing musical notes. Only two similar cases would seem to have been recorded. One was observed by Dr. Cassels at Glasgow, the other by Dr. Christinneck in the clinic of Prof. Schwarze at Halle. Prof. Grüber did not enlarge on the features of this interesting case; but it certainly affords food for suggestive thought in reference to treatment of diseases of the ear. Hitherto, the labyrinth was considered a sort of *noli me tangere*; but now we see that the entire cochlea may be missing, and yet the aural powers be retained. On the other hand, it is not yet quite certain whether in the above case paralysis of the auditory nerve may not eventually occur.

RESPONSIBILITY IN SANITARY MATTERS.

DR. SIEVEKING presided at the last of the lectures which the Sanitary Assurance Association gave at the Parkes Museum in December, 1884. The lecturer was Mr. Mark H. Judge, who delivered an address on Public and Private Responsibility in Sanitary Matters. The question to be considered was whether any good could come out of attention to the conditions under which we live. Was it correct to believe that sanitary reformers, from Moses and Mahomed down to Edmund Parkes and Florence Nightingale, were in the right in attaching importance to the state of man's surroundings? It was to the physician that we must turn in order to set these questions at rest; from him must the architect learn how to build residences fit to live in. De Chaumont and Erichsen were quoted to show that sound sanitary conditions were essential for the maintenance of health, if not for the very existence of life itself. Some of the chief sanitary defects in houses were pointed out. It was urged that the sanitary engineer, and not the sanitary architect, should be concerned in the construction and ventilation of the main sewer. Mr. Judge criticised the powers conferred on local boards and surveyors in saying that their qualifications did not fit them for regulating the sanitary arrangements of residences. The responsibility of the householder should be increased. Fresh legislation was required on these matters.

THE EXAMINATION OF SURGEONS-MAJOR.

WE are sorry that our contemporary, the *Army and Navy Gazette*, does not approve of our views on the subject of the examination of surgeons-major in the army prior to selection for promotion, but we see no reason to change the opinions which we have throughout consistently advocated. The subject is one of great importance to the army. Promotion by seniority had a long trial in the medical department, and was found wanting. It was condemned by the Royal Commission appointed to inquire into the organisation of the department after the Crimean war, and subsequently by Lord Cranbrook's Committee. By the Royal Warrant of 1879, based on the report of that committee, all promotions above the rank of surgeon-major are to be made by selection for "merit and ability," and the grounds of the selection are to be stated in writing. This clearly bars all claim to promotion to the higher grades on the ground of mere seniority, and devolves upon the head of the department a serious responsibility. It manifestly involves the principle of the selection of the fittest, and not merely the exclusion of the incompetent. But to enable the Director-General to carry out this principle it appears to be necessary that he should have the means of testing the qualifications of the officers from among whom the choice is to be made. And we know of no method in which this may be effected so likely to answer the purpose as the examinations which have been authorised. It is true that the confidential reports furnish a certain amount of information as to the general fitness of an officer for promotion, but they are deficient on points of great importance. The system of promotion by selection, if honestly carried out, cannot fail to exert a very beneficial influence upon the medical officers by holding out an inducement to them to keep themselves well up in professional knowledge, especially in its bearing upon military sanitation. It will, in fact, supply that stimulus which in civil life is brought into operation by professional competition, and the want of which has hitherto been most injurious to the army. In the Indian service this has been less felt, as the numerous civil appointments have brought out the varied qualities of the medical officers and have been looked to as a reward for good work, but under the blighting system of seniority in the Army Medical Service there has been no such inducement to intellectual culture or professional study. We sincerely trust the system of promotion by selection, impartially administered, may be followed by the result which we anticipate, of obtaining for the army an efficient, zealous, and thorough administrative medical staff.

"SCENT."

AN attempt is being made to account for the remarkable powers exhibited by some dogs on the presumption that "scent" is a faculty *per se* altogether distinct and different from the sense of smell. This is, as all physiologists must know, a misconception. The truth is that each species of animal has some specially developed faculty of relation by which it is, more than by other faculties, placed *en rapport* with the external world. The differences are

great even among small classes of beings; for example, among dogs some use sight more than smell—as the greyhound. The sense of smell is, however, generally developed to a high pitch among those animals which have in a state of nature to hunt for their prey, or to avoid predatory enemies. There is nothing, that we can perceive, difficult to understand in the intelligence exhibited by the lower animals. The scientific doctrine of evolutionary development affords a satisfactory solution of every problem, and renders the facts plain to see.

OVER-PRESSURE IN SCHOOLS.

A SUB-COMMITTEE on "Over-pressure," appointed by the Conference of Representative Managers of London Board Schools, has arrived at the conclusion that while the effects of over-pressure are not wide-spread, they exist, and that measures of relief are needed. It is recommended that home lessons should be minimised, and altogether prohibited in the case of children below the third standard; that "keeping in" should never be resorted to except for punishment; that inspectors should be less examiners than inspectors; and that other changes in administration should be employed to reduce the evil which, in a limited degree at least, is admitted to prevail. We do not anticipate any great result from these "recommendations," even if they be adopted. What is needed is a total and immediate abandonment of the forcing system and complete discontinuance of the wholly indefensible practice of giving children lessons to learn at home. Children ought never to be worried with lessons out of school hours. While the active business of education is in progress in school, a child may be taught all that it is necessary or proper to teach it. The supposed need of lessons "out of school hours" is a product of the ignorance which prevails as to the physiology of mental processes, and especially of that reception and retention of ideas which we call *memory*. School managers and teachers need themselves to be put to school to learn the rudiments of science in connexion with these matters, and not until they have been thus instructed will they be fit or trustworthy as regards the education of the young.

THE GENESIS OF THE HUMAN MIND.

MR. ROMANES in two recent lectures delivered at the London Institution has placed the facts and primary inferences which form the bases and data of discussion on this subject in a particularly clear light. The force of his logical argument has, of course, carried him to the conclusion that the mind, like the body, of man, has been produced by the same process that has been adopted in the development of the animals below man—namely, *evolution*. No other issue was possible to an honest scientific inquiry. The difference between man and the brutes below him in the scale of mental power and faculty is one of degree, not of nature or even of area. Mr. Romanes laid great stress on the objection that man alone has been endowed with the *logos*—that is, the gift of speech or language; but, as he afterwards showed, this position is really untenable, because history and observation combine to prove that while, on the one hand, the evolution of intellect proceeds *pari passu* with the acquisition of the power of the tongue in *man* as a genus and as an individual, on the other hand, reason and "instinct" are increasingly apparent in the brutes in proportion as they develop the faculty of expression or communication among themselves and with man. We know how horses and dogs "speak" in a language of their own, communicating their desires to each other and to man; and evidence is not wanting that the conceptions they form are more than simple or immediate. They not only observe, but reason. They adapt means to ends, forming purposes and carrying them out. They make estimates of character, and not unfrequently go far beyond these lesser performances, exhibiting sympathy, regard, protective care, and even exercising ingenuity in effecting their purposes. The *logos* is as much a matter of development as anything else. It is not a gift, but an acquisition, and may be lost, as we see it lost now and again, in the case of any individual who is deprived of the educational advantages of association with those who have acquired the power of cultured speech, and are able to communicate it.

YELLOW FEVER ON BOARD A NEWCASTLE STEAMER.

OUR Newcastle correspondent, in reference to the arrival in the Tyne last week of a steamer whose crew had suffered most severely from yellow fever contracted on the West Coast of Africa, states that, in addition to the six men mentioned as having died at sea, another seaman landed at Dartmouth has also died, as well as one sent on to Liverpool, who has since succumbed from the effects of yellow fever. The *Iolanthe* carried seventeen hands, and the only members of the original crew on arrival in the Tyne were the mate and a boy. The original captain and the survivors of the original crew left the vessel at Havre, at which port she had called. Every precaution has been taken as to the disinfection of the ship and the clothes of the deceased seamen by the Tyne port sanitary officers.

THE MARY WARDELL CONVALESCENT HOME.

A VERY touching appeal is made by Miss Mary Wardell on behalf of her convalescent home for scarlet fever at Brockley-hill in the *Daily News* of Dec. 31st. She writes: "Ever since the day of its opening by the Princess of Wales, on July 14th, the flow of contributions which I was able by my personal efforts to raise has ceased. ..... Whilst doing the work of a matron, and so saving the salary of that official, I have often been obliged to undertake the work of a household servant, for which I am physically unfit, and at the same time I have endeavoured to fulfil the almost impossible task of combining a secretary's duties with these other occupations. All this I would willingly and cheerfully do had I at the same time encouragement and support from others; but the result of all my sacrifice of time, strength, and such means as I can rightly dispose of without injustice to others, is that I must borrow money to meet the expenses of the few months during which I have been receiving patients, and must shortly close the home with a heart-broken sense of failure and wasted life and energies." We are sincerely sorry to hear that there is any danger of the good work which Miss Wardell is doing coming to an end for want of support. Charitable hearts and means to do good happily abound in our midst, and we are sure there are many who will hasten to make the glad new year still more glad by assisting Miss Wardell to obtain the £5000 for which she so eloquently and so pathetically pleads.

THE PRICE OF COCAINE.

WE are glad to hear that there has been a considerable reduction in the price of the new anæsthetic, several well-known firms offering to supply the hydrochlorate of cocaine in small quantities, and for a limited period, at eighteenpence a grain. The supply is still far from abundant, and it is not improbable that in a week or two it will regain its original price. In the United States it at first commanded a dollar a grain. Messrs. E. Merck & Co., of Darmstadt and London, have, with great liberality, placed a considerable quantity of the alkaloid in the hands of one or two well-known observers in order that its properties may be thoroughly investigated.

A HOSPITAL TRAIN.

THE Italian War Office in concert with the Society of the Red Cross and the Upper Italy Railway Company has succeeded in putting up on wheels a hospital train which must prove of the highest utility, not only in belligerent operations, but also during the invasion of an epidemic. The train in question concluded on Saturday last a trial trip, or more truly a triumphal progress, at the Roman terminus, after having journeyed through Piedmont, Liguria, Lombardy, Venetia, Emilia, Tuscany, Umbria, and the Neapolitan territory, in all of which provinces it was visited by the leading authorities in medicine and engineering, and subjected to criticisms which must conduce to the perfecting of its appointments. The Upper Italy and Venetian Railway companies having provided a number of carriages on the Swiss, or rather the American, model - that is, with a corridor passing down the length of the carriage, and in continuous communication with the similar corridors of the other carriages of the train, the Red Cross Society undertook in conjunction with the Army Medical Department to furnish the material necessary to convert such a train into a thoroughly appointed clinical ward. This has been effected by ranging beds on each side of the corridor, the beds being slung in hammock fashion so as to reduce to a minimum the vibration or the shock inseparable from the sitting compartments in present use, the beds themselves consisting of palliasses laid on frames of highly elastic metal net work, suspended on supports of wood and leather. The heating of the carriages as well as their ventilation have also been skilfully secured, and a trained staff of attendants effect the speediest possible removal of the discharges of the patients, and the subsequent disinfection and deodorising. Special carriages are reserved and appointed for the hospital stores, the compounding of medicines, and the *armamentarium medico-chirurgicum*, while others on the Pullman system are attached to the train for the accommodation of its professional *personnel*. Experience will suggest improvements on this first specimen of a most necessary adjunct to the resources of army and State medicine; but even as now appointed the hospital train recently on view at the great seats of medical and engineering science throughout Italy reflects the highest credit on its promotors and constructors. Had such a means of transport been lately in working at the various scenes of choleraic infection in the Peninsula, how swiftly the removal and isolation of the sick could have been effected, and how successfully the disease, inducing panics, might have been foreclosed.

DEATH CERTIFICATES IN CASES OF INJURY.

A REPORT of an inquest lately held at the Southwark coroner's court appeared in the *Evening Standard* of Dec. 19th. It was there stated that Mr. Philip P. Jackson, M.R.C.S., had been severely censured for having given a certificate of death from natural causes, "he knowing the whole facts of the case," and amongst them that the deceased woman, Carney, had been subjected, as was alleged, to intentional violence at the hands of her son-in-law. Had this been correct, without doubt he would have merited the condemnation he received; but Mr. Jackson meets the accusation by saying that he only saw the deceased a few hours prior to her death, and further, that he did not consider the bruising on the face as having conduced to or accelerated death. Unwisely, as we think, he was not called at the inquest, where statements derogatory to his professional character were made without his having the opportunity of denying their truth. The verdict of the jury, however, was in accordance with the certificate, "the post-mortem proving nothing whatever to the contrary." Whilst of opinion that Mr. Jackson acted with perfect *bona fides*, and erred only by way of omission, we cannot help feeling that he would have acted more circumspectly had he informed the coroner of his own view of the case, and of the rumour that deceased had been roughly handled. From his own showing the patient was too ill to undergo a satisfactory examination, and it therefore became the more necessary to free himself from all responsibility in the matter. Had the post-mortem examination revealed serious injury to the brain, it could scarcely be contended that the case was not essentially one for inquiry, or that death was not accelerated by the injury.

INFECTIOUS AND CONTAGIOUS DISEASES IN SCHOOLS.

AT the meeting of the Medical Officers of Schools Association, to be held at the Medical Society's Rooms on the 7th instant, a code of rules for the prevention of infectious and contagious diseases in schools will be brought forward for approval by the Association. The Code is divided into five sections, as follows:—Section 1. General hygiene, comprising drainage, water and milk supply, the duties and undivided responsibility of a medical officer, &c. Section 2. The infirmary, its construction, arrangement, and management. Section 3 deals with the medical examination of scholars on admission, &c. Section 4 points out the general precautions to be adopted against the introduction and spread of disease; and Section 5 the measures to be adopted when an infectious disease has appeared in a school. Two appendices follow, one containing forms of certificates suggested for use with reference to the prevention of infectious disease in schools, and the other giving a list of disinfectants, with rules for their use The rules are practical and plain, and it is to be hoped that the result of this labour on the part of the Association may prove not less useful to parents and guardians, who deal with the home life of the children, than to school authorities, since without the sympathy and intelligent co-operation of the former no real progress can be made in this great department of preventive medicine.

TROPHONEUROSIS (?) OF THE TESTICLE.

A CASE which may possibly be an example of a trophoneurosis is recorded by M. Lemmonier in the *France Médicale* of December 25th. The patient was a young man aged nineteen, who sustained severe injury to the skull after a fall from a height of about six feet. Hemiplegia of the right side, and rapid atrophy of the testicle and of the right upper limb are the chief phenomena recorded. There was considerable disturbance of consciousness, but ultimately the patient appears to have recovered to a large extent. The hemiplegia was probably dependent upon compression by blood poured out as the result of the fracture of the base of the skull. No other conditions seem to have been present to account for the rapid wasting of the arm or testicle. Nélaton and others have spoken of the possibility of atrophy of the testicle resulting from causes acting at a distance.

A TROUBLESOME PATIENT.

ABOUT a fortnight ago a young man, well-dressed and in apparently good health, applied for advice at the Middlesex Hospital. He was seen by the resident medical officer, to whom he complained of pain in the perineum, which he attributed to a long-standing gleet. He was then referred to the house-surgeon, who carefully examined him, but failed to find anything the matter with him, and he was accordingly given an order to see the assistant-surgeon on his next day of attendance and told to leave the hospital. This, however, he refused to do, and expressed his intention of remaining. After sitting in the waiting-room for two

hours he was again requested to leave, and it was explained to him that he could not be taken into the hospital for such a trivial ailment, and that the assistant-surgeon would see him. He then lay down across the door and behaved in a foolish manner so that the hospital porter was told to remove him. This he did, when the man turned round and knocked the porter down, stating that he only desired to be arrested. He was then given in charge, and the magistrate remanded him for a week in order that his case might be examined more fully in the infirmary, and he has since been discharged.

THE PAY PRINCIPLE IN THE NORWICH HOSPITAL.

AT this hospital the proposed rule providing for the admission of pay patients has, after a good deal of discussion, been rejected. The Rule was as follows:—

"A limited number of patients above the ordinary class of hospital inmates may be received. Such cases must be specially in need of hospital treatment, and shall bring an introduction from a medical man. Patients of this class shall pay at the rate of £1 1*s.* per week, or such other amount as the Board of Management shall determine."

We are glad that this rule has been thrown out. Not because we deny that there are many people in need of hospital accommodation who can afford to pay, but because there seems to us a grave tendency to turn the poor out of our hospitals and to make increasing accommodation for those who can pay. This tendency needs resistance as far as the existing hospitals are concerned, which are not too much, but all too little, for the accommodation of those who cannot pay. The great development of the teaching of nursing makes it easy to establish in every great town houses for the accommodation of those who can afford payment.

EMOTIONAL JAUNDICE.

THE possibility of the dependence of jaundice on emotional disturbances in some cases is unquestionably great. The case quoted by Murchison of the soldier who became rapidly jaundiced as the result of being restrained from wreaking his vengeance on a certain individual is probably familiar to most of us. M. Rendu has recorded the circumstances under which a young woman aged twenty-five, convalescent from puerperal peritonitis, became jaundiced within three hours after an unsuccessful attempt to catheterise the bladder. The yellow colour of the skin remained four days, and the urine contained bile pigment one day longer. The sudden onset and rapid disappearance of the jaundice are in favour of its being of neurotic origin, but the presence of subsiding puerperal peritonitis rather vitiates the evidence for the case as one of emotional jaundice.

OPEN SPACES IN LONDON.

THE Metropolitan Public Garden, Boulevard, and Playground Association, in its report for the year which has just closed, affords good reason to hope that its vigorous work of reform will long survive that exhausted term. During the two years of its existence it has added many open spaces to those hitherto devoted to recreation within the metropolis. The areas thus gained have been for the most part the sites of disused burial-grounds. These and the other vacant spaces have been laid out as gardens and playgrounds, and furnished with appropriate gymnastic apparatus. There is still, however, much to do. Numerous graveyards unused for burial, for building, or for any purpose, public or private, save to guard the remains long since committed to them, invite the offices of the Association to remodel them in the interest of the surrounding districts. It would seem that the natural destiny of all enclosed land within the urban area, irrespective of its history, is to be built upon. The hygienic reasons which have weighed with us in condemning this practice have been reiterated in former articles. We therefore the more frankly and earnestly commend the wise action of the association, and we doubt not that the public and the ecclesiastical proprietors will see reason to forward its salutary work.

PROMPT SUPPLY OF SURGICAL APPARATUS FOR THE POOR.

THE absurd rules of the otherwise excellent Societies which exist for supplying the poor with surgical apparatus have led other charitable bodies into the same line of work. The council of the Hospital Sunday Fund devotes 4 per cent. of its collection to this purpose, which for the current year will amount to £1400. Now the Charity Organisation Society have established a department for the prompt and economical supply of these instruments on the same plan as the Convalescent Department. It is to be regretted that the Surgical Aid Societies should give too good reason for this competition of other bodies, which have quite enough special work of their own to do. Provided fit cases are selected, it must be allowed that the supply of surgical instruments is a most urgent and commendable form of charity.

STREET ILLNESS AND BAD POLICE AND WORKHOUSE REGULATIONS.

NEITHER the police authorities nor the authorities of the Kensington Workhouse appear to advantage in the account of the inquest on Robert Thomas Roylance Wigington, aged sixty-four, which was reported in *The Times:* –

"Early on the morning of December 22nd he was found insensible outside the booking-office at Earl's-court Station. He was taken in a cab to the infirmary of the Kensington Workhouse, where he was refused admission. He was then taken to the police-station, when he was found to be dead. Police-constable Dixon deposed to seeing the deceased taken to the infirmary. The authorities there refused to admit him. The Coroner: Why did you not call a doctor at first? Witness: Because he was in a cab and not in the road. If he had been in the road I should have called a doctor. The Coroner: A nice distinction when life or death is concerned."

There is some confusion here. But whether Mr. Wigington was found in the road or in a cab is a matter of unimportance, compared with the folly of police and workhouse rules, which hinder the nearest assistance being cheerfully and promptly offered to a dying man. Can anything be more absurd than for a workhouse infirmary, supported by public rates, to refuse admission to a dying man, or for a policeman to go wandering about London with such a man before consulting the nearest doctor?

A NEW OTOSCOPE.

A NEW otoscope, arranged by M. Rattel, was exhibited at the Académie de Médecine last month. It is lighted by means of an incandescent wire made of manufactured charcoal, which gives an illumination equal to two candles. An accumulator giving a current of electricity of a certain intensity may feed the lamp for at least six hours. The reflector is represented by a portion of an ellipse constructed in such a manner that one of the foci corresponds to the site of the lamp and the second to the extremity of the instrument, which has pretty much the form of an ordinary funnel-shaped otoscope. The light can be extinguished or graduated to any degree. The opening through which the observer looks is large enough to permit the passage of all the ordinary aural instruments.

COLLECTIVE INVESTIGATION IN GERMANY.

THE results of the inquiry into phthisis set on foot by the Collective Investigation Committee of the Verein für innere Medicin (Berlin) will be published in the *Zeitschrift für Klinische Medicin*. Dr. Meyerhoff will report upon the question of contagiousness, Dr. Oldendorff on that of heredity, Drs. Leyden and Frantzel on curability, and Dr. Kalischer on the passage of pneumonia into phthisis. The scheme of this inquiry was, it may be remembered, far more complete and exhaustive than the corresponding one undertaken in this country, and it will be interesting to learn its conclusions. The next subject proposed for investigation by the committee is the communicability of contagious diseases of children through a third person (or thing). The diseases named are: scarlet fever, measles, whooping-cough, variola, varioloid, diphtheria, and mumps.

THE DARENTH SMALL-POX CAMP.

COMPLAINTS as to the administration of the Darenth small-pox encampment continue to be made, notwithstanding the statements of Sir E. Currie that they are unfounded. These complaints relate in the main to irregularity in the supply of meals, dirty beds, and absence of proper clothing. The Asylums Board managers have certainly spared no expense in their efforts to provide everything needful for the sick, and in their own interests it would be well that a committee of investigation should be appointed. More than one complaint has been made to the effect that patients have died without any proper record of the death being kept, and relatives have in consequence suffered considerable distress of mind. If the local administration is defective it should be forthwith modified, and the first step will be to find out where the fault really lies.

HOSPITAL SUNDAY.

THE annual meeting of the constituents of the Hospital Sunday Fund, on the 23rd ult., passed off most satisfactorily, the Lord Mayor presiding. His speech was in good taste, and showed kindly sympathy with the objects of the fund. Several vacancies in the council were filled up. The entire absence of opposition or even criticism at the meeting should not be construed by the council as meaning that there is no more for them to do in the way of extending this great movement, but, on the contrary, as an encouragement to devise yet further means for developing it.

THE UXBRIDGE TRAGEDY.

ON the afternoon of the 30th ult. the governor of Her Majesty's prison of Newgate, Captain Sutton Kirkpatrick, received an intimation from the Home Office that the sentence of death passed upon Elizabeth Gibbons for the murder of her husband at Hayes, near Uxbridge, at the last sessions of the Central Criminal Court, had been respited. It is understood that those who have prepared the petition to the Home Secretary on behalf of the condemned woman will not rest their efforts to obtain an investigation into the circumstances of the case by the law advisers to the Crown, with the view of determining whether there has not been a wrongful conviction.

THE LONDON FEVER HOSPITAL.

WE most gladly repeat our commendation of this institution as one worthy to be held in remembrance. It is very meritorious and very impecunious. In the last thirty-eight years it has admitted 48,348 cases—and what cases! and at what relief and advantage to private families!

THE following very serious statement is made in the *Western Morning News* regarding the excessive punishment of boys on board Her Majesty's ship *Northumberland*, whose crew includes 140 boys. "During the late cruise, and also since her arrival home, the amount of corporal punishment inflicted is truly horrifying. Almost every morning batches of the boys, from half a dozen to eighteen in number, have been caned or birched, chiefly the former, with great severity, the sufferers often being removed in various stages of insensibility. The ship's corporal has been repeatedly enjoined to greater vigour by the officer superintending these floggings, and the bruised and bleeding backs of the boys, and their writhings and howls, have testified to the vigour of his arm. The frequency and severity of these punishments have become a matter of loud protest among the able-bodied blue-jackets, who are themselves protected by law from similar tortures. The offences for which these almost daily whippings have been inflicted are said to be of a trivial character." This, if true, discloses a very dreadful state of affairs. The matter demands immediate investigation by the authorities.

FROM the report of the examination made by Colonel Sir Francis Bolton, C.E., of the water supplied by the several metropolitan water companies during the month of November, it appears that the water sent out by the companies drawing their supply from the Thames again exhibited an unusually small proportion of organic matter for this season of the year, as did also the water derived from the Lea. All the waters were delivered in a clear and bright condition.

MESSRS. WOOD AND CO., the publishers of Lafayette-place, New York, our agents for the United States and Canada, have received an order from the Medical Purveyor of the American Government to supply the Medical Department of the United States Army with THE LANCET, so that every regimental depôt, commencing with our present issue, will receive regularly a copy of the journal.

AT a meeting of the Oldham Sanitary Committee on the 18th ult., Dr. Hill, the medical officer of health, reported that the severe and sudden illness from which some twenty or thirty persons had suffered after attending a public tea recently held in the town was attributable to the ingestion at the entertainment of unsound cured tongues.

AT a public meeting in connexion with the University College (London) Medical Society, to be held on Jan. 14th next, Prof. Ray Lankester will deliver a lecture on Bacteria and Bocilli in their relation to Putrefaction and Disease. After the lecture there will be a demonstration of Micro-organisms and Methods of Cultivation.

DR. JAMES RUSSELL, F.R.C.P., J.P., Senior Physician to the General Hospital, Birmingham, has resigned that office, after twenty-six years' service on the honorary staff of the institution. Dr. Russell's friends will be glad to hear that his retirement from public work has been occasioned by the pressing calls of consulting practice.

A NUMBER of scientific men in Paris having founded a club called "La Science," for the purpose of dining together at stated times, recently entertained M. Chevreul. M. Pasteur has been nominated chairman of the next dinner. A similar club was instituted six years ago under the name of "Banquet de la Presse scientifique."

PROF. GUIDO BACCELLI has been elected President of the Roman Academy of Medicine.

THE vestry of St. Luke's are determined to oppose the proposal of the Governors of Dulwich College to hand over seventy-two acres of land to the Metropoitan Board of Works for the purpose of a people's park. A deputation which waited upon Mr. W. M. Torrens, M.P., pointed out that the land of Dulwich was devised by Alleyne for the joint benefit of the parishes of St. Luke, St. Botolph, Bishopsgate, St. Saviour, Southwark, and St. Giles, Camberwell; and therefore to give the land as stated would be a serious loss to the parishes named, more especially St. Luke's. The deputation further showed a plan whereby a recreation ground might be provided for St. Luke's from the price at which the Dulwich land was valued—namely, £21,000.

THERE appears to be urgent need of a mortuary in the parish of St. Botolph, Aldgate. A correspondent writing to a contemporary on Dec. 30th, complains that the body of a man "who hung himself on Sunday, still lies in the room, just as it was found, and this too in the largest common lodging-house in the London Docks," and adds, "the same complaint is always made at every inquest held in this parish."

IT will have been seen by an announcement in our advertising columns that the Commissioners in Lunacy have issued notices that in future they will, in all cases of violation of the laws respecting the detention of persons supposed to be insane, proceed by indictment against the offending parties.

DR. WILLIAM MARSHALL, who acted as medical attendant to the late Duke of Albany prior to his Royal Highness's marriage, died on the 22nd ult. at Crieff, Perthshire, in the fiftieth year of his age. The deceased retired from the service of Her Majesty several years ago, in consequence of failing health.

To avoid as far as possible risk of infection in surgical procedures, Professor Esmarch is stated by the *St. Petersburger Med. Wochenschrift* to have discarded wooden operating tables and to employ only those made of metal. All the instruments used are nickel-plated and metal-handled.

THIS afternoon (Friday) the President and Vice-Presidents of the Royal College of Surgeons of England will receive a deputation from the Association of Members of the College respecting certain changes in the interest of the Members to be suggested in the new Charter.

IT is stated that the members of the Imperial Academy of St. Petersburg caution the public against the frequent repetition of experiments in "thought-reading," as a number of serious cases of illness are reported daily by the press.

THE death is announced of Dr. Grimm, Staff Surgeon and Body Physician of the German Emperor, and Chief Agent in the Organisation of the German Military Sanitary System.

WE understand that one of the members of the English Cholera Commission, Dr. Heneage Gibbes, has returned to London.

GIFTS TO HOSPITALS.—One hundred and twenty of the principal hospitals in town and country have, we understand, received, within the last few days, a donation of Messrs. Cassell and Company's periodicals for the use of the patients.

Pharmacology and Therapeutics.

THE "M'K. AND R." CAPSULED NITRO-GLYCERINE PILLS.

NITRO-GLYCERINE is such a valuable therapeutic agent that it is not surprising that new methods of administering this powerful remedy are constantly being introduced. The "M'K. and R." capsuled pills, from their small size and attractive appearance, are likely to meet with much favour. They have been tried in angina pectoris, asthma, neuralgia, and a number of other complaints in which the drug is recommended, and have been found most useful. The covering is perfectly soluble, dissolving in the mouth in about thirty seconds, and there can be no doubt as to the activity of the contents, for they produce as much headache as the most ardent pharmacologist could desire.

THE "MAORI" CIGARETTES.

We have received specimens of Dr. Douglas's "Maori" cigarettes for the relief of asthma, chronic bronchitis, and hay fever. They obviously contain nitre, and probably henbane and stramonium. They burn freely, and we are not surprised to hear that they have been found useful. It is said that they have been used with success in the wards of the Royal Infirmary at Edinburgh. They may be obtained from T. Kennedy Douglas, M.B., C.M., 2, South St. John's-place, Perth.

VALOID OF COCA.

The introduction of a new and reliable preparation of coca will be hailed with satisfaction. The valoid is made from the fresh leaves of the coca plant, each drachm representing that weight of the crude drug, including the whole of the alkaloidal and other principles. It has been extensively employed of late, and, curiously enough, is found to exert a double physiological action. In small doses it acts as a sedative promoting sleep, whilst in larger quantities, such as three or four drachms, it stimulates the nervous system and induces an increased capacity for mental exertion. It has been used with much success in sleeplessness arising from overwork or worry and anxiety, and also in the treatment of impotence, spermatorrhœa, and a number of allied diseases. It has no toxic action.

OIL OF PEPPERMINT.

Oil of peppermint would appear to be a useful application for burns, according to Dr. Brame. The part burned is first immersed in water, and then the oil is painted on by means of a fine camel-hair pencil. The chief effect is the immediate relief of the pain.

ANTIPYRIN.

Dr. Ernst of Zurich reports that he has observed in five cases the occurrence of a rash during the administration of the new antipyretic "antipyrin." The eruption, which occurred on the chest, stomach, and back, is described as consisting of small reddish irregularly circular spots, resembling pretty closely those of measles. The spots are confluent, and the patches formed, being separated by areas of sound skin, present the appearance of a rose marbling. When pressed the red colour disappears, leaving a brown pigmentation. The eruption increases in intensity of colour for about five days, and then the red gives way to a brown colour, and the rash finally disappears though the use of the antipyrin be continued.

TEUCRUM SCORDIUM.

Teucrum scordium, the water germander, is reported to have been used both locally and internally in the treatment of piles. Mr. Murjohn has prepared a liquid extract by exhausting the powdered herb with dilute alcohol, the preparation being of a blackish-green colour and given in doses of one or two fluid drachms. A soft dark green extract is obtained by evaporating this extract, which has been used in the form of pills, one grain being combined with two grains of the powdered herb. An ointment for local use is prepared by mixing one part of finely powdered herb with nine parts of vaseline.

VERBENA HASTATA.

The blue vervain has been found by Dr. Weber to be an excellent sudorific. The root, which has a bitter astringent

and nauseous taste, is the most active part of the plant, but the leaves and flowers may also be used. A fluid extract is made in the usual manner, the dose of which is one-half to one fluid drachm.

ERGOT.

Ergotinic acid, sphacelinic acid, and cornutine are the active principles of ergot according to Dr. R. Roberts. Ergotinic acid, even in large doses, did not produce very marked effects. Sphacelinic acid is a powerful poison, the amount obtained from thirty grammes of ergot being sufficient to kill a fowl, and that from 200 grammes to kill a small pig, death resulting from gangrene; this principle is probably the cause of the gangrene which sometimes attends the use of ryebread containing ergot. It causes a tetanic action in the uterus. Cornutine is the only energetic alkaloid that occurs in ergot. The ergotinine of Tanret has no physiological effect according to Dr. Roberts; but five milligrammes of cornutine causes salivation, vomiting, diarrhœa, and active movements of the uterus in warm-blooded animals, as well as contraction of the bloodvessels and a rise in the blood-pressure. The latter effects are also produced by sphacelinic acid. The only preparations which should be used are those containing these two principles.

REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

[FIRST NOTICE.]

THIS report is issued as a separate volume forming the supplement to the Thirteenth Annual Report of the Board, and it deals with the medical transactions of the Board during the year 1883. Vaccination appears, notwithstanding the noisy agitation of a few, to be making fairly steady advance, the children certified to be vaccinated numbering about twenty times those who, so far as certificates are concerned, remain unvaccinated; and with reference to the prevention of small-pox, it is interesting to note that the mortality from that disease amongst the unvaccinated children and the vaccinated was about as 200 to 1. Calf lymph continues to be distributed to registered medical practitioners, the number of points and tubes sent out during the year being 9311 and 2151 respectively. Mr. Shirley Murphy, the Assistant Director of the Calf Lymph Establishment, reports on similar institutions in Holland and Belgium, and he is inclined to regard the results obtained in the former country as superior to those seen in London, the difference being in his opinion due to the better age and finer skins of the calves used in Holland. The animals sent to Lamb's Conduit-street are at times too young, and they have often hardly got over the hardships to which they have been exposed by long land and sea journey, and it must be our endeavour to overcome this and allied difficulties if the local results are to be the best that can be obtained. A typical instance is given of the inquiries which are made by the Medical Department into allegations of injury by vaccination. The report is by Dr. Page; it goes to show that the allegation was wholly groundless, and that a sickly child which happened to have been in every sense of the word successfully vaccinated, subsequently suffered from diarrhœa and sickness, was then drugged with soothing syrup, and died.

The inquiry which is being conducted by Dr. Ballard into the subject of the prevalence of autumnal diarrhœa in England is still in progress, and one very interesting aspect of the investigation is referred to in the report under consideration. This has to do with the relationship which exists between the disease as seen in England (and which is often called choleraic diarrhœa) and the malady which prevails as an endemic in some parts of India, and which at times spreads over various parts of the world. It is more than probable that some of the conditions under which the two diseases appear are either alike or have much in common, and it is by no means improbable that the difference between them has to do with a modification in those conditions which is brought about by some such circumstance as climate. Any light that can be thrown upon this obscure question will well repay the long-continued study which is being devoted to the diarrhœa investigation. With reference to cholera itself, a brief account of the Egyptian prevalence of 1883 is placed on record by Dr. Buchanan, who expresses a regret, which many will share with him, that the regular examination of prevalences of cholera and other Eastern diseases is no longer maintained. Formerly this work was ably carried out by Mr. Netten Radcliffe, and it appears more than strange that the country which, of all others, has the greatest interest in studying the etiology of cholera and other Asiatic diseases should maintain at its central bureau so "limited" a staff that it has become necessary to abandon a work of the highest importance to the interests and well-being of some millions of its citizens. Reading between the lines, it is quite evident that Dr. Buchanan does not consider that the results of the inquiry which was instituted by the British Government into the etiology of the Egyptian outbreak were at all conclusive. He points out that the importation of the disease by means of pilgrims returning from Mecca was not even excluded; he is of opinion that the mere occurrence of cases of a choleraic disease in various parts of Egypt by no means justifies the inference that cholera had long been endemic in that country; and he regrets that the application "of those inductive methods of investigation which are familiar to the practised sanitary inquirer of England" were not brought to bear upon the prevalence in question.

The volume contains a number of the more interesting reports issued by the several medical inspectors, investigations as to diphtheria taking a prominent position amongst those which are thus permanently placed on record. They have all been commented on by us as they have been issued, and we will only add, with regard to them, that we are glad to notice that an increasing number of these reports now find their way into the Medical Officer's Annual Report.

The more scientific part of the volume contains a further contribution by Dr. Burdon Sanderson on the products of putrefaction in relation to the prevention of disease, the investigation being conducted in connexion with researches which are being made into the value of different methods of disinfection. Dr. Klein also takes part in this inquiry, his efforts being directed to ascertain how far various substances have the ability to destroy that power which the microphytes of disease have of directly or indirectly producing disease. There are few inquiries which are more needed than this one, for at present but little more is known as to the respective merits of the various "disinfectants" than what their inventors choose to assert for them, and in one sense it is to be regretted that the final conclusions cannot more rapidly be arrived at. The difficulties attendant upon the investigation are, however, great, and they must be dealt with step by step. Mr. Dowdeswell also contributes to this part of the report a paper on the Etiology of Charbon Symptomatique, and its relations to other allied diseases. For the present we postpone detailed comment on this group of scientific papers.

REPORT OF THE SPECIAL INDIAN CHOLERA COMMISSION.

THE *Gazette of India* publishes the following report, dated Calcutta, Nov. 28th, 1884.

From Dr. J. M. Cuningham, Sanitary Commissioner with the Government of India, to the Secretary to the Government of India, Home Department.

I have the honour to submit, for the information of the Government, a short preliminary report by the English Cholera Commission of the results of their inquiries during their visit to India.

2. Their complete report will be passed through the press when they arrive in England, and submitted to the Under-Secretary of State for India.

3. It will be observed that Messrs. Klein and Gibbes' conclusions are altogether subversive of the statements advanced by Professor Koch as to the so-called "comma bacillus" being the cause of cholera.

From Drs. E. Klein and Heneage Gibbes to the Surgeon-General and Sanitary Commissioner with the Government of India. Dated Calcutta, Nov. 27th, 1884.

We have the honour to report that the investigations which we have hitherto carried on in Bombay and Calcutta have yielded the following results:—

1. The statement of Koch that "comma bacilli" are pre-

sent only in the intestines of persons suffering from or dead of cholera is not in accordance with the facts, since "comma bacilli" occur also in other diseases of the intestines—e.g., epidemic diarrhœa, dysentery, and intestinal catarrh associated with phthisis.

2. The "comma bacilli" in acute typical cases of cholera are by no means present in such numbers and with such frequency as to justify Koch's statement that "the ileum contains almost a pure cultivation of comma bacilli."

3. The "comma bacilli" are not present in the tissue of the intestine or elsewhere.

4. The "comma bacilli" in artificial cultivations, carried out by one of us (E. K.), do not behave in any way differently from other putrefactive organisms.

5. Mucus flakes of the ileum, taken out soon after death from typical acute cholera, contain numerous mucus corpuscles, many of them, filled with peculiar minute straight bacilli. The same bacilli occur also outside the mucus corpuscles. They are never missed even when the "comma bacilli" are.

6. These small bacilli have been cultivated by one of us (E. K.), and they do not behave differently from putrefactive organisms. They are not present in the tissues of the intestine or any other tissue.

7. No bacteria of any kind, and no organisms of known form and character, occur in the blood or any other tissue.

8. A good many experiments have been carried out by one of us (E. K.), with the following results:—(*a*) Mice, rats, cats, and monkeys were fed with rice-water stools, with vomit, with mucus flakes of the ileum, fresh and after having been kept for twenty-four to forty-eight hours. The animals remained normal. (*b*) Inoculations with recent and old cultivations of "comma bacilli" and the small straight bacilli, as well as with mucus flakes, were made into the subcutaneous tissue, into the peritoneal cavity, into the jugular vein, and into the cavity of the small and large intestine of rabbits, cats, and monkeys; but the animal remained perfectly well and normal.

9. The material which we have had hitherto at our disposal has been very good and abundant, and, as far as the microscopic work goes, we do not think we shall require any more material. We therefore propose concluding our inquiry by the beginning of December, and hope soon after to return to England.

THE CULTIVATION OF THE BACILLUS OF TUBERCLE.

DR. CREIGHTON has expanded the criticism passed on Dr. Koch's method of cultivating tubercle bacillus at the last meeting of the Royal Medical and Chirurgical Society into a *brochure*, the substance of which is as follows:—In the first place Dr. Creighton points out that Koch has not availed himself in such cultivations of the "dry" method, whereby alone exclusion of foreign germs can be secured. Koch has sought, not to separate the tubercle bacilli from admixture with other organisms, but only to detach them from the tuberculous matter in which they occur. He takes a piece of tubercle from the dead-house, strips off its outer layers, and crushes the surface in corrosive sublimate. The mass thus prepared is placed on the surface of solidified blood serum in a test-tube and crushed into fragments, the tube being then kept at a temperature of 98° F. for three weeks; at the end of that time some of the dried scales which have formed on this surface are transferred to another test-tube and treated as before. Dr. Creighton contends that, although Koch gives no further information on the process, he "has departed from the first principle of pure cultivation of micro-organisms—namely, the principle of transferring only a minimal or fractional quantity from one test-tube to the next." He includes Mr. Watson Cheyne in the indictment, who followed the same process, and who assumed that thereby the original cheesy matter is wholly destroyed, the organisms alone remaining. There is no evidence, he maintains, to show that the final inoculations contained bacilli and nothing else. The substance put into the test-tubes was tubercle "and it came out tubercle, baked, indeed, to crusts and scales, but still tubercle." Moreover, the method actually employed by Koch hindered the free development of the bacilli, as it prevented the growth of other micro-organisms. Schüller, who adopted fluid cultivations direct from tubercular matter, obtained cultures of various organisms (which must have been descended from those originally present in the tubercle), and yet failed to inoculate animals with the disease by means of the bacterial fluid thus obtained. Dr. Creighton's closing remarks sufficiently indicate his position and the distrust he has of the bacilli being proved by Koch's experiments to be the specific virus of the tubercle. He says:—

"The truth is that Dr. Koch was scrupulously careful to keep his bacilli always dry and always cohering in what he calls 'colonies.' His attempts to grow them in fluids were half-hearted; the bacilli were involved in brittle conglomerates or crusts, after long exposure of the tubercular tissue to heat, and they never had a fair chance to multiply in fluid. If they had been set free in a suitable fluid medium, they would certainly have multiplied, and multiplied with marvellous rapidity. *But they would have been no longer motionless rod-shaped organisms.* They would have been moving bacteria and micrococci; we know that much from the experiments of MM. Toussaint, Klebs, and Schüller. To retain the bacillar form it is necessary to keep the organisms in tubercle always dry. That must have been Dr. Koch's main reason for practising a dry method of 'pure' cultivation, which resembled his original dry method in little more than the name. He certainly succeeded in making the rod-shaped organisms to multiply as rod-shaped organisms; he avoided the awkward breach in their morphological identity, which would have confronted him if he had let them multiply in fluids, as they are more than willing to do. At the same time he unfortunately retained in the crusts and scales the detritus of the pieces of tubercle with which he set out. Thus, under the guise of his dry method, he not only succeeded in preserving the morphological identity of the bacilli as they mostly occur in tubercular degenerations within the body, but he also preserved among his inoculation material a sufficient quantity of that which we must still consider to be alone infective in tubercle—namely, the virus of the tubercular tissue itself."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 4353 births and 3386 deaths were registered during the week ending the 27th ult. These registered numbers were, owing to the Christmas holidays, very considerably below the average weekly numbers. The annual death-rate in these towns, which had been equal to 24·4, 22·6, and 21·6 per 1000 in the preceding three weeks, further declined last week to 20·2. During the thirteen weeks ending last Saturday the death-rate in these towns averaged 21·4 per 1000, against 23·0 and 21·2 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 13·2 in Birkenhead, 13·8 in Plymouth, 15·9 in Salford, and 16·2 in Brighton. The rates in the other towns ranged upwards to 26·8 in Hull, 28·3 in Preston, 28·4 in Sunderland, and 32·2 in Leicester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 393 and 398 in the preceding two weeks, did not exceed 311 in the week ending last Saturday; these included 69 from whooping-cough, 67 from measles, 54 from scarlet fever, 36 from small-pox, 34 from "fever" (principally enteric), 28 from diphtheria, and 23 from diarrhœa. No death from any of these zymotic diseases was returned last week in Plymouth, Birkenhead, or Huddersfield, whereas they caused the highest death-rates in Leicester, Preston, and Sunderland. The greatest mortality from whooping-cough was recorded in Wolverhampton, Oldham, and Halifax; from measles in Preston, Cardiff, and Leicester; from scarlet fever in Cardiff and Sunderland; and from "fever" in Preston and Norwich. The 28 deaths from diphtheria in the twenty-eight towns included 20 in London, 2 in Norwich, 2 in Liverpool, and 2 in Sunderland. Small-pox caused 47 deaths in London and in its outer ring of suburban districts, 3 in Liverpool, and 1 in Brighton. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1019 and 1026 on the preceding two Saturdays, further rose to 1076 at the end of last week; the admissions declined, however, to 161 last week, from 263, 190, and 244 in the previous three weeks. The Highgate

Small-pox Hospital contained 95 patients on Saturday last, against 99 at the end of the previous week; 14 cases were admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined from 511 to 416 in the preceding four weeks, further declined to 370 last week, and were 206 below the corrected weekly average. The causes of 82, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Newcastle-upon-Tyne, Norwich, Plymouth, Derby, Birkenhead, and Halifax. The largest proportions of uncertified deaths were registered in Sheffield, Blackburn, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 31·8, 28·3, and 26·9 per 1000 in the preceding three weeks, rose again to 29·6 in the week ending 27th ult., and was no less than 7·4 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 19·5 and 20·4 in Leith and Edinburgh, to 32·1 in Paisley and 34·7 in Glasgow. The 691 deaths in the eight towns included 34 which were referred to measles, 26 to whooping-cough, 16 to scarlet fever, 14 to "fever," 11 to diarrhœal diseases, 9 to diphtheria, and not one to small-pox; in all, 110 deaths resulted from these principal zymotic diseases, against 140, 109, and 108 in the preceding three weeks. These 110 deaths were equal to an annual rate of 4·6 per 1000, which was 2·7 above the mean rate from the same diseases in the twenty-eight English towns. The 34 deaths from measles in the Scotch towns were within two of the number in the previous week, and included 30 in Glasgow. The fatal cases of whooping-cough, which had been 30 and 25 in the previous two weeks, were 26 last week, of which 14 occurred in Glasgow and 3 in Edinburgh and in Greenock. All the 16 deaths from scarlet fever, showing a considerable increase upon recent weekly numbers, were returned in Glasgow. The 14 deaths referred to "fever" also exceeded the numbers returned in recent weeks, and included 10 in Glasgow and 3 in Aberdeen. Seven of the 11 deaths attributable to diphtheria also occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 231, 190, and 178 in the preceding three weeks, further declined to 174 last week, but exceeded by 66 the number returned in the corresponding week of last year. The causes of 116, or nearly 17 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 28·7 and 34·1 per 1000 in the preceding two weeks, declined again to 26·6 in the week ending the 27th ult. During the thirteen weeks ending last Saturday the death-rate in the city averaged 29·4 per 1000, the mean rate during the same period not exceeding 19·8 in London and 19·7 in Edinburgh. The 179 deaths in Dublin last week showed a decline of 50 from the number in the previous week, owing in great measure to the Christmas holidays causing delay in registration; they included 13 which were referred to the principal zymotic diseases, against 24 and 18 in the preceding two weeks. Of these 13 deaths, 7 resulted from scarlet fever, 5 from "fever" (typhus, enteric, or simple), 1 from diphtheria, and not one either from small-pox, measles, whooping-cough, or diarrhœa; they were equal to an annual rate of 1·9 per 1000, the rate from the same diseases last week being 1·7 in London and 0·8 in Edinburgh. The fatal cases of scarlet fever in Dublin, which had steadily declined from 16 to 6 in the preceding five weeks, rose to 7 last week. The 5 deaths referred to fever also exceeded the number in the previous week. Five inquest cases and 6 deaths from violence were registered in the city, and 61, or more than a third of the deaths, were recorded in public institutions. The deaths, both of infants and of elderly persons, showed a decline from the previous weekly numbers. The causes of 30, or nearly 17 per cent., of the deaths registered during the week were not certified.

ENGLISH MORTALITY IN 1884.

It will be nearly a month before the Registrar-General issues his quarterly return for the last three months of 1884. The English death-rate during that period may, however, be approximately estimated from the thirteen weekly returns, which give the mortality statistics for nearly nine millions of population living in the twenty-eight large towns dealt with in that return. On the hypothesis that the death-rate in England and Wales last quarter bore the same relation to the rate recorded in the twenty-eight large towns, as was the case in the last quarters of 1882 and 1883, it may be estimated at 19·0 per 1000, and to have been 1·6 below the mean rate in the ten preceding corresponding quarters. The death-rate in the third or summer quarter exceeded the average, owing to the heat that prevailed in the first half of August; but in each of the other quarters of the year the rate was considerably below the average. The mean rate for the four quarters of the year was 19·3 per 1000, against 18·9, 19·6, and 19·5 in 1881, 1882, and 1883, and was 1·4 below the mean rate in the ten years ending 1883. Thus the marked decline in the English death-rate which has been coincident with the operation of the Public Health Acts of 1872 and 1875 is being fully maintained. The English death-rate was practically stationary during the thirty years 1840-70 at 22·4 per 1000, signifying that the sanitary achievements of that period had only been successful in counteracting the baneful effect, from a health point of view, of the rapid increase of urban aggregation. In the five years 1871-75 the rate slightly declined to 22·0, and in the following five years, 1876-80, fell to 20·8. In the first four years of the current decade, ending on the 31st ult., a further marked decline occurred, and the mean annual death-rate in these years did not exceed 19·3. The death-rate in each of those four years was lower than in any of the forty-three previous years of civil registration. It was shown in a paper recently read before the Statistical Society that the effect of the reduction in the English death-rate in the five years 1876-80 upon the duration of life in England, if continued, would be to add two years to the life of every male, and three and a half years to the life of every female born. The continued and increased reduction of the English death-rate in the last four years is therefore an event the national importance of which cannot well be over-rated.

THE SERVICES.

Surgeon-Major Sir Samuel Rowe, K.C.M.G. (Governor and Commander-in-Chief of the Gold Coast Colony), has been appointed Governor and Commander-in-Chief of the West Africa Settlements; Surgeon-General J. Hindley, C.B., has been appointed to succeed Surgeon-General R. Gilbourne as principal medical officer on the Staff of Lieut.-General Sir A. Alison, K.C.B., at Aldershot.

BENGAL MEDICAL ESTABLISHMENT. — Surgeon-Major Archibald Hamilton Hilson, M.D., to be Brigade Surgeon; Surgeons Matthew Denis Morcarty, Gordon Price, M.D., Edward Bovill, Bartholomew O'Brien, M.D., George Albert Dundas, Henry Walter Hill, Zalnoor Allee Ahmed, M.D., William Arthur Gilligan, William Edwin Griffiths, to be Surgeons-Major.

MADRAS MEDICAL ESTABLISHMENT.—Surgeons Edward Levinge, Augustus Napoleon Rogers-Harrison, Lionel Beech, Henry Plunkett Esmonde-White, to be Surgeons-Major.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon W. H. Colahan, to the *Assistance;* Staff Surgeon G. B. Murray, to Plymouth Hospital; Staff Surgeon Thomas Bolster, to the *Triumph;* Surgeons F. H. Trevan and R. J. Lawson, to the *Triumph;* Surgeon John Hunter, to the *Indus;* Staff Surgeon Henry Scanlan, to the *Nankin*, additional; Fleet Surgeon Robert Nelson, to the *Monarch;* Surgeon Samuel Johnson, to the *Briton;* and Surgeon Herbert W. G. Doyne, to the *Agincourt.*

THE DRAINAGE OF THE LOWER THAMES VALLEY.—The Local Government Board inquiry with reference to the applications of various constituent authorities for separation from or dissolution of the Lower Thames Valley Main Drainage Board was resumed for the eleventh day at Kingston on the 30th ult. Evidence was adduced on behalf of the joint board and in favour of the scheme of Sir Joseph Bazalgette for the total diversion of the sewage of the district to Crossness, immediately contiguous to the southern outfall of the main drainage works of the Metropolitan Board of Works. The inquiry was again adjourned.

"Audi alteram partem."

THE EXTINCTION OF CHOLERA EPIDEMICS IN FORT WILLIAM.

To the Editor of THE LANCET.

SIR,—My attention has been called to an article under the above heading in THE LANCET of December 13th. Before entering on the subject of that communication I particularly desire to obviate any misapprehension that may arise in regard to it. I have not dwelt on the importance of having a pure water-supply, because it appeared to me superfluous to do so. No one entertains any doubt on that subject; it forms an elementary principle of sanitation, and is accepted as an axiom in sanitary science. But that is not the point. The question raised was whether the spread of cholera can be exclusively attributed to the use of contaminated water, and whether such water "communicated" cholera to a population drinking it by virtue of its containing a specific cholera contagium. I contend that this latter has never been proved; nor is it likely to be, seeing that it would be inadequate to explain all the facts, and is inconsistent with some of them. It would certainly surprise me if a regiment drawing its supply of drinking-water from an impure source did not, other things being equal, during an epidemic of cholera, suffer disproportionately from that disease as compared with another regiment supplied with pure water. But if I may rely upon the recorded experience of others, fortified with some results within my own knowledge, I should say that the habitual, or even occasional, use of a saline aperient at such times would have a still more prejudicial effect. And, if I may be pardoned the digression, I may remark before the comma bacillus culminates in a full stop, that it is very difficult to reconcile the notion of its enormous multiplication and development in the intestines being the cause of cholera, with the well-grounded, as I think, observations of practical men that diarrhœa is very prevalent in times of epidemic cholera, and that one's only chance of curing the disease is to arrest it in its initial stage—in other words, to shut up the morbific agent inside the intestines of its unfortunate host. I do not, of course, assert that all cases of diarrhœa develop into collapsed cholera; how many may do so is another thing.

It has been again and again put forward that the relative immunity of Fort William from cholera of late years is attributable to the introduction of a pure water-supply, and by a pure water-supply was meant the Municipal water. That is certainly what I have been told, and understood from documents to which I have referred. Many years ago, however, I came upon an extract from the proceedings of the Government of India in the Military Department, dated 11th October, 1871, in which it is stated that the Government did not consider it expedient to incur the expenditure necessary for the introduction of the municipal water because "the troops in Fort William had proved for years past *remarkably healthy*." (The italics are mine.) It is now asserted that there was another and improved water-supply completed in 1865 to which this result must be ascribed. So far as I can gather, however, water from the same source viz., rain water more or less filtered through clean grass ground and collected in the Havildar's tank was used up to the introduction of the municipal water, but some additional means for filtering it were added and its distribution was by hydrants instead of by mussacks. Of course, the increased facility for obtaining this water would lessen the liability of native servants to obtain it from other sources. The complaint about this tank water was not as to quality, but that the supply was limited and apt to fail. "The tank water is pronounced by the chemical examiner to Government to be remarkably pure and wholesome. This might be expected from the fact of its being rain water stored up and secured from all contamination."—(*Vide* Report, dated 19th June, 1860, signed by the Brigadier Commanding, the Garrison Surgeon, and officiating Garrison Engineer, Fort William.)

Moreover, if the past records of this garrison[1] be examined

[1] The statistics given in the accompanying table have been compiled for the most part from Dr. Bryden's works and from the Reports of the Sanitary Commissioners with the Government of India.

Table showing the Average Strength and Number of Deaths from Cholera among European Troops in Fort William between 1826 and 1882.

Year.	Average strength.	No. of deaths.	Year.	Average strength.	No. of deaths.

1852	—	20	1881	926	1
1853	—	13	1882	963	1
1854	—	—	1883	854	1

* The statistics of troops from 1850 to 1857 are very imperfect.

it will be found that at a date long antecedent to the introduction of the improved water—viz., between 1830 and 1840—the mortality from cholera was very low. If we take seven consecutive years within that period, as compared with seven years intervening, 1865 to 1871, between the introduction of the two water-supplies to the fort, we find that there was only a small difference between the average annual death ratio from cholera for the two periods—viz., 2·97 per 1000 for the earlier, and 2·18 for the latter period. During the ten years from 1870 to 1879 there has been a marked decline in the mortality from cholera among the European troops in the Bengal Presidency as a whole; the average mortality has been 4·18 as compared with 9·24 per 1000 in the ten previous years; and it is not asserted that these improvements in health and water-supply have been conterminous; contrariwise, the present state of that supply in Bengal is still alleged by some to be the sole cause of epidemic cholera. But if we compare the ratio of deaths from cholera among European troops in Calcutta and the neighbouring garrisons, we find that from 1866 to 1874 in Fort William it was 2·18, as against 1·15 in Dum-Dum and 0·79 in Barrackpore per 1000; and from 1872 to 1882 it was 1·13 in Fort William, 0·74 in Dum-Dum, and 0·51 in Barrackpore per 1000. Moreover, one and the same cause cannot well be productive of two opposite effects. The introduction of the municipal water into Fort William has, it is alleged, caused the relative immunity from cholera enjoyed by that garrison; but I believe I am correct in stating that its introduction into Alipore gaol in water carts deriving their supply straight from the hydrants was followed by a mortality from cholera in 1879 alone equal to that of the previous seven years, during the greater part of which period, at any rate, the convicts were supplied from the local tank. By a parity of reasoning, we are as much justified in drawing a similar deduction in the one case as in the other; and yet we know that one would be false. May not both?

Take the town and district of Dacca. A new water-supply was introduced into the former and a considerable fall took place in the cholera death-rate, which might fairly have been attributed to that as a cause; but there was contemporaneously a great improvement in the district which had not had the benefit of the new water-supply.

Now, let us advert to an example in which great pains had been taken to secure a good water-supply for a service of steamers. Dr. Crombie, now at Dacca, a competent and experienced man, kindly sent me a letter he had received from the emigration medical officer at Goalundo, dated April 9th, 1881: "It is rather strange that just as we were talking of the occurrence of cholera amongst emigrants and the water-supply arrangements on board the Assam steamers, a severe outbreak of cholera was going on on board one of those steamers. Since then we have had one of the severest outbreaks that has occurred for years, seventy-two cases with thirty-four deaths, out of a population of less than four hundred. The water arrangements were perfect, and no fault whatever could be found with the steamer."

A great many changes and improvements have been effected in Fort William besides the introduction of the water, beginning with the construction of those airy, lofty blocks known as Dalhousie Barracks in 1859, and including great improvements in drainage; in brief, there has been a sanitary improvement all round. But have we any assurance, after all, that the garrison at Fort William may not again suffer from cholera? It is more than I should care to affirm.

If it can be said that a pure water-supply will be absolutely protective against an epidemic of cholera at Fort William, this must be pushed to a logical conclusion, and the same thing can be postulated of every other place. Now, to say that the state of the water-supply will account for the recent epidemic in Egypt, France, Italy, and Spain, requires more boldness of assertion than I possess.

The question of the improved medical history of the garrison of Fort William is a very interesting and instructive one, and worthy of exhaustive investigation. There are two methods in which this may be made. One, accepting the fact, to examine into all the causes likely to account for it; the other, to accept the theory of water contamination as a fact, and then to see whether the results can be ascribed to its absence. I prefer the former method.

I am, Sir, yours truly,

J. A. MARSTON,
Deputy Surgeon-General.

Dec. 30th, 1884.

TREATMENT OF INTESTINAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—Anyone who reads Mr. Steele's letter in your last number can only come to the conclusion that, when I said in the debate on obstruction of the bowels at the Liverpool Medical Institution that the treatment by "rest, starvation, and opium had for many years been the recognised treatment," I purposely overlooked the labours of Mr. H. O. Thomas in this direction, as set forth in his book published last year. I certainly had no such intention. It has been my privilege, both in speech and in writing, to give my highest tribute of praise to Mr. Thomas for the admirable work he has done in another department of surgery, and therefore it is very unlikely that I would seek to deprive him of his just due in this. Mr. Thomas, however, in his speech at the Medical Institution arrogated no such claims for himself as are advanced by your correspondents, but modestly told how the real credit of the method of treatment under discussion was due to none other than Sydenham. Surely Mr. Thomas must pray to be saved from his friends. I most gladly acknowledge the valuable work done by him in pushing the doctrine of rest and opium, even although to some he may almost seem to have done so to an extreme point. He has drawn men's minds forcibly to the question, and has put it upon a better defined basis. He has shown how milk is a bad form of nutriment, and has exposed the positive dangers of certain forms of mechanical treatment. For this he deserves, and has, our grateful thanks.

But if I am asked where I learnt the principles of rest and opium, I reply that I first knew of them from Laycock and Christison in 1863; although even before that I had heard Miller tell how Liston used to say that the bowels in cases of obstruction were to be opened, not with purgatives, but with opium and the lancet. In 1867 appeared Brinton's remarkable little book, and from that date I should think there is not a single teacher in Great Britain who has not taught on his lines. There has certainly not been one at the Liverpool School of Medicine, for I have asked every one of them what they have been in the habit of teaching. Looking over Dr. Cameron's notes for his lectures twenty years ago, when lecturing on obstruction, I find the following headings:—"Opium the remedy; constipation a necessary and curative symptom (principle of rest); purgatives to be avoided." Dr. Waters, in his remarks at the Institution, said that until acute symptoms had quite subsided his treatment was "absolute rest, complete, or almost complete, abstinence from food, and the exhibition of opium and belladonna." In Aitken, Bartholow, Roberts, and Quain the same text will be found preached. In Ziemssen, Leichtenstern will be found following the footsteps of Brinton. Gentlemen who cannot see anything of the rest, starvation, and opium treatment in these works are determined not to see. Mr. Treves, in the very latest book on the subject, has been accused of knowing nothing about this treatment. I read in it: "It is worse than useless to attempt to feed these patients by the mouth. The patient may have ice to suck to relieve the sense of distressing thirst, but, apart from this, all food should if possible be administered by the rectum. There is certainly no one drug of more use and value in cases of intestinal obstruction than opium."

Personally I may say that during the eighteen years I have practised in Liverpool I have seen as many cases of intestinal obstruction as falls to the lot of most men of my own age, and I never heard of any other treatment being employed, so soon as it was once discovered that the case was one of so-called obstruction, and not a mere ordinary attack of constipation. And here is where Mr. Steele quite fails to apprehend the matter. In cases of acute obstruction, with symptoms similar to those of a sharply strangulated hernia, only one treatment can be and is employed, and none other—viz., rest, starvation, and opium, and, failing these, operation. But under the name chronic obstruction we are unfortunately obliged to class a variety of cases which differ infinitely in character from those which are produced by utterly irremediable causes to those which are termed merely "functional" cases. Now, every case of chronic obstruction begins just like any simple case of constipation, and, in the first instance, is to be treated as such. Things would come to a remarkable pass if the minute a man missed his daily motion for two or three times

he was to be subjected to the treatment for serious obstruction when a dose of castor oil or a tumbler of warm water in the rectum was all he wanted. As regards the use of calomel, any physician of experience will tell Mr. Steele that minute doses of that drug are often most valuable in allaying distressing irritability of the stomach, while they cannot possibly add to the dangers of the obstruction. Concerning nutrient enemata in certain very protracted cases of obstruction, some sustenance, however slight, must be given to the patient, otherwise he will die of exhaustion before his cure is effected. Experiment has incontestably proved that with the artificially digested aliments now in use life can be wonderfully supported by rectal feeding, while bowel irritation is reduced to a minimum. Concerning the use of inflation of the bowel in certain cases of intussusception one must remember that much that has been tried in that way has been in the form of experiment. And legitimate experiment too; for, after all, even rest and opium are mightily unsuccessful in really serious cases of obstruction, however much they may do for those cases which would have got well under any treatment, like the cases of diphtheria which some practitioners are always curing in vast numbers. And there is a limited number of cases where a low intussusception has been made out with certainty in children, where inflation undoubtedly has been most successful, a fact which cannot be controverted.

I rather regret that Mr. Steele, in his eagerness to champion Mr. Thomas, should have found it incumbent upon him to charge an old teacher and friend with lack of generosity to a fellow surgeon, but to that charge I have pleaded not guilty. I must, however, with much deference to the greater knowledge of Mr. Steele, adhere to my statement that for many years, rest, starvation, and opium have constituted the recognised treatment for intestinal obstruction by all intelligent and well-educated practitioners, and that this treatment was not for the first time heard of in 1883. I am, Sir, your obedient servant,

Liverpool, Dec. 1884. W. MITCHELL BANKS.

To the Editor of THE LANCET.

SIR,—In the recent interesting debate at Liverpool upon the question of the treatment of intestinal obstruction, Mr. Mitchell Banks is reported to have made the following statement: "The second difficulty consisted in the fact of spontaneous recovery under the opium, rest, and starvation treatment, which has now for many years been the recognised practice." (THE LANCET, Dec. 6th.) I am somewhat surprised to find that no less than three of your correspondents take very decided exception to this statement. They dispute the assertion that the treatment named is a recognised mode of practice. Mr. Steele of Liverpool and "A Provincial Man" pay me the high compliment of observing that the measure is not generally recognised, because it is "not even alluded to" in my recent work upon intestinal obstruction. Mr. Steele, moreover, claims that this mode of treatment "was undoubtedly originated by Mr. H. O. Thomas." In venturing to meet the objections that these gentlemen have raised, I might be allowed, in the first place, to endorse Mr. Banks's statement. With regard to the allusions to my work that have been so kindly made, I can only say that I have endeavoured in the book named to give especial prominence to this very measure. I have urged it—speaking especially of acute and subacute cases—not only as the primary and elementary basis of all treatment, but as a measure to be adopted by routine. In the chapter on treatment I deal first with "the feeding of the patient," or, as the paragraph would be as well headed, with "the starvation of the patient," and then proceed to the use of "opium." The question of rest falls under the consideration of these two factors in the treatment.

In detailing these measures I did not imagine that I was dealing with any "new thing," but rather that I was expressing as clearly as I was able the recognised measures adopted in the first treatment of intestinal occlusion. With regard to the claim made on behalf of Mr. Thomas, I regret that I did not see his able and original monograph until the MS. of my book was entirely in type. The chief feature of Mr. Thomas's work appeared to me to consist in a very skilful and vigorous advocacy of the measure now in question—a measure the value of which I considered had been for years generally recognised. I cannot agree with Mr. Thomas in considering this particular treatment as final and all sufficient. It appears to me to be the best primary routine treatment, and the best introduction to such other and more active measures as the needs of particular cases may possibly demand. I am, Sir, yours faithfully,

Gordon-square, W.C. FREDERICK TREVES.

THE BRITISH MEDICAL BENEVOLENT FUND.

To the Editor of THE LANCET.

SIR,—You have often allowed me at this season of the year to plead in your columns the cause of the widow and fatherless, and of the old, broken-down or unfortunate who depend on the British Medical Benevolent Fund for some small addition to their comfort or, very frequently, for relief from actual want, and help was never more needed than at this moment. The scheme of the charity is well known in the profession. It has two departments, one for giving annuities of £20 or £26 (10*s.* a week) to worn-out members of the profession, their widows or daughters, after the age of sixty; the other for the relief of pressing necessity by donations. The annuitants, who are maintained by the proceeds of investments, now number fifty-three, but it is very rarely that anyone can be elected under the age of seventy. The donations are furnished out of money collected year by year, and it is on this department of the fund that the greatest pressure comes. The number of applications during the year has been 241; the amount distributed over £1900, in sums varying from £1 to £24. Examples of the cases coming before the Committee at the monthly meetings are as follows:—F.R.C.S., aged seventy-four, of excellent character, hears of the fund when he has broken into his last sovereign; he gets an immediate advance of £2 and a further grant of £15. The daughter of a medical man, a nursery governess, applies on behalf of her brother, himself qualified, who is dying of phthisis; £12 is voted, payable in weekly instalments; he dies before it is exhausted. Medical men in failing health, widows suddenly left destitute with young children or striving bravely to bring up a numerous family, daughters of medical men worn out or broken down as governesses—these are our everyday applicants. A few are kept from actual pauperism or starvation entirely through the fund. The profession has responded most liberally to special appeals for exceptional cases. This is natural and praiseworthy, yet I cannot but fear lest the chronic, prosaic misery of the clients of this fund be lost sight of. Our exchequer is nearly empty, and I again ask those who can afford it for contributions to enable us to continue our help to the less fortunate of our brethren. They will be most thankfully received by Mr. Field, 31, Lower Seymour-street, or by

Your obedient servant,

31, Seymour-street, Portman-square, Dec. 31st, 1884. W. H. BROADBENT, M.D., Treasurer.

THE UXBRIDGE TRAGEDY.

To the Editor of THE LANCET.

SIR,—In reference to the above case, I feel confident that the writer of the paragraph in your last issue was not himself present at the trial, and did not hear the medical evidence; and I would suggest that it is scarcely fair to condemn that evidence—given by Mr. Parrott and myself—as being contrary to pre-existing knowledge, upon the very imperfect, and in many respects entirely erroneous, reports in the daily papers.

The writer says: "The inferences of the medical witnesses were at variance with similar known facts in other cases on record, in which a shot has been fired by a suicide in the interval between the infliction of a mortal wound, even of the heart, and death." First, with reference to your mention of the heart wound, it would seem that the writer has fallen into the same error as many well-intentioned correspondents to the daily papers in assuming that, in order to explain the case as one of suicide, it is necessary to presuppose the possible self-infliction of other wounds after that of the heart. There is no necessity to make any such difficulty, for, viewing the case as one of suicide, there was a much more simple explanation, and one which I fully allowed—namely, that the heart wound was the last of the

three inflicted on the front of the body and face of the deceased. And not only did I allow of such a possibility, but I further stated that an examination of one of these three wounds—that beneath the clavicle—convinced me that it, at any rate, had been received before the heart was damaged. The sequence of the different injuries was thus arranged in the manner most favourable to the prisoner, and she benefited by whatever doubt there might have been on this score. You will thus see, Sir, that if the heart wound is considered as being the last of the three inflicted on the front of the body, the duration of life after its causation is not a very material point. Nevertheless, the statement that in my opinion death would result therefrom "within two minutes" was made by myself with a full knowledge that life has been prolonged, and that recovery even has followed, after some wounds of the heart.

Your paragraph is certainly vague—perhaps intentionally so—but it implies that the prisoner was not allowed by the medical witnesses the benefit of the doubt as to the possibility of the deceased firing more than one shot into himself, and, to anyone who has read the reports in the daily papers, it undoubtedly would convey the idea that I had denied the possibility of the self-infliction of all of the three wounds found on the front of the body and face of the deceased. Will you allow me to state very definitely that, both at the Uxbridge Sessions and at the Central Criminal Court, I did allow the possibility of the self-infliction of the third wound in spite of the injuries caused by the two others previously inflicted. Then, as to the wound in the back, the writer says: "Moreover, a wound in the back is peculiarly likely to be self-inflicted if the suicide falls forward or on his side while the arm still clutching the pistol is convulsively drawn, stiffened, and by the fall twisted back."

Do you really suppose, Sir, that any reasonable man would doubt that "*a wound in the back*" could be self-inflicted? The question is, Could this particular wound be self-inflicted? I said, and say again, most emphatically that it could not, and yet the writer of your paragraph, who never heard my reasons for this opinion, nor saw the wound, has no trouble in explaining the difficulty which neither the counsel for the defence nor any of the jury were able to solve.

I think, Sir, you will see that the charge made against the medical evidence has been made hastily and on insufficient grounds. Other matters went to the jury besides those reported in the daily papers, and I would ask both you and your readers to reserve their judgment until I am able to put the real facts before you.

Yours truly,

Queen Anne-street, Dec. 30th, 1884. ANTHONY A. BOWLBY.

*** We did not assume, as Mr. Bowlby seems to think, that in order to explain the case as one of suicide it is necessary to presuppose the possible self-infliction of other wounds after that of the heart," but obviously wrote with the purpose of illustrating what may be done after a fatal wound of a vital organ. We do not, therefore, deem it necessary to correct an imaginary error. Mr. Bowlby's reference to "well-intentioned correspondents to the daily papers" lies outside of the issue raised in our last week's annotation; however, we only hold ourselves responsible for what appears in our own columns. Again, Mr. Bowlby takes exception to the statement that "a wound in the back is peculiarly likely to be self-inflicted if the suicide falls forward on his side, while the arm still clutching the pistol is convulsively drawn, stiffened, and by the fall twisted back," and with veiled sarcasm *hints* that we were so puerile as to descant on a self-evident fact. It was not the mere self-infliction of a wound in the back, but the *method* of such an act under certain conditions to which we intentionally and deliberately drew attention. Our information of what transpired at the inquest and trial was received through the usually accredited channels. At present we can only express our regret that Mr. Bowlby should feel injured by what he conceives a misrepresentation of his evidence as to fact and opinion. Our comments were made in the interests of justice, and in the belief that the reason why "neither the counsel for the defence nor the jury were able to solve the difficulty" was that they were not clear as to the possibilities, probabilities, and certainties of the case in its medical aspect.—ED. L.

CHARCOT'S DISEASE.

To the Editor of THE LANCET.

SIR,—The recent discussion at the Clinical Society has excited so much attention, especially with reference to the distinctive character of the affection, that the description of the following case may be of interest. E. C——, forty-two, single woman, was admitted into the wards of the Doncaster Infirmary, under the care of Dr. Sykes. She was an inpatient some years ago with extensive ulceration of the thighs, believed to be of a syphilitic character, and the cicatrices left bear out the supposition. She is a very stout woman, with a fixed rosy complexion and a peculiarly fatuous expression of countenance, constantly smiling in an idiotic manner. She speaks slowly and with a stutter, as if her tongue were too large for her mouth. She says that she has never had rheumatism, but gives a past history of sore-throat and skin eruption. Eight years ago her mother died, which broke up the home and caused her much anxiety, and she was obliged to go into the workhouse. Soon afterwards her hands began to feel numb, the sensation spreading up both arms, and her fingers and hands were swollen so that their use was much affected; her knees next began to swell, without pain, and her legs failed her. She had frequent attacks of giddiness, and could only perform her household duties with difficulty. Her memory became bad and she was subject to sudden failings of sight. Her skin is dry, and hangs in folds over the body. All over the back and also on the abdomen are little tumours, some pedunculated, others sessile, beneath the skin, of the fibroma molluscum type. The arms, particularly the right, are œdematous, and also the legs. Cutaneous sensibility is impaired all over the body. A needle can be plunged into the arms or hands at any point without causing pain. The hands have a clumsy "spade-like" appearance, the fingers curved backwards, and the phalangeal joints seem in a state of partial dislocation. There is no thickening of the articulation of the fingers, wrist, or elbow. She can give a grip of fair and equal power with both hands. There is some difficulty of movement of the left shoulder, and on rotation distinct crepitus is elicited from the joint. The knee-joints are irregularly swollen, no synovitis is apparent, the left larger than the right, and the extensor muscles of the thigh appear to be wasted. The general appearance of the joints is "knotty," like an old tree, and, as she lies in bed, as if there was a partial dislocation backwards and inwards of the leg on the thigh. There are several hard nodular enlargements round the joint, one or two being freely movable. The movements of the joint are quite free, almost more than naturally; no pain is caused by manipulation, nor is any crepitus to be detected. There does not appear to be any enlargement of the ends of the bones themselves. If the thigh be supported the leg swings freely. She is very slow in all her movements. She can walk by herself by taking great care, but if she shuts her eye she reels, and if she then moves forwards she falls. She complains of occasional shooting pains in the head, and also in the abdomen; the latter seem to be of a constrictive character, and occasionally very acute. The area of cardiac dulness is considerably increased on percussion, the heart-sounds are very feeble, but no bruit is audible; the pulse is slow and weak. The urine contains no albumen. The catamenia have always been regular but excessive. She is highly emotional, and laughs or cries on the slightest occasion. She has been treated with iodide of potassium, without any improvement to the general condition.

I have not had the opportunity of seeing any of Professor Charcot's cases, nor of having the benefit of the experience of those who have attended his clinique, but I imagine the above to be a similar condition to that to which the name of the distinguished Frenchman has been assigned. The syphilitic element is very plain in this case, although the condition of the joints does not resemble anything usually met with in that disease. The ataxic symptoms are very distinct, and there are several points in the case that bear a strong resemblance to the symptoms of myxœdema, of which I saw several cases in St. Thomas's Hospital, under Dr. Ord. The condition of the left shoulder-joint is just like an

ordinary case of rheumatoid arthritis. In several cases of myxœdema I noticed that the patients described their symptoms as following on some severe mental trouble, such as bereavement or reverse of fortune, of which this patient also made a point. I cannot see why we should go out of our way to make out nineteenth-century diseases. Darwin, Hutchinson, and men of that type, have simply put together facts that have been staring us in the face for generations, but for want of men of "collective investigation" nature, the gold was passed over by hundreds, before it was picked up by them.

I am, Sir, yours obediently,

J. G. MARSHALL, M.D. Cantab., M.R.C.S.,
House Surgeon, Doncaster Infirmary.

Dec. 26th, 1884.

LUNACY REFORM.

To the Editor of THE LANCET.

SIR,—In the *résumé* in *The Times* of Saturday last of the supposed provisions of the New Lunacy Bill, there is one point that should not be allowed to pass without comment. I do not refer to the locum tenens' duties of the Deputy Commissioners, which are too impracticable to need contradiction; but to the barefaced suggestion to rob the medical profession of the two plums of the New Lunacy Board—viz., the posts of Chairman and Deputy Chairman. The new Commissioners, who must have served for years with the committees of asylums, must surely have had more experience of this particular kind than the well-connected but briefless barristers who are usually promoted to such posts.

The general education of the medical man is equal to that of the barrister, and the technical is certainly superior; while years of experience in the practical working of the Lunacy Laws must render a lunacy commissioner much better fitted for the post of chairman than a barrister totally unacquainted with the subject. It is the duty of alienists, as well as of the profession at large, to make every possible exertion to prevent an injustice, which at the same time is a slur and an insult to the profession.

I am, yours truly,

PSYCHOLOGIST.

Hanwell, December, 1884.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE NEWCASTLE INFIRMARY.

I HAVE mentioned in previous letters that a movement was on foot for the extension of the Newcastle Infirmary by the erection of a new wing. I am happy to tell you that the proposition has fallen rather flat, as it was felt by many that the wants of the city and district could best be met by a new building in a more desirable situation than that at present occupied by the institution, which was open to many grave objections, and scarcely at all up to the requirements of modern sanitary science. Lately a meeting of the medical staff has been held, and the members were unanimous in recommending a new site and building in preference to any temporary or patchwork expedient. I believe also that the necessary funds will be found with greater facility now that a new building is likely to be determined upon.

"THE PHILADELPHIA CASE."

In a former letter I referred to this question as exciting a good deal of attention among the friendly societies of the North, and indeed outside them by the profession and the public. It is now settled, and in the following manner: both parties agreed to submit the matter to medical arbitration, and to abide by the decision. Drs. Clarke, Newton, and Hume—with Mr. Hardcastle, surgeon of this city—were appointed, and after a careful consideration they found that the miner's death took place from enteric fever, and was not accelerated by the accident for which it was sought to recover compensation. The case is instructive as showing how, in a matter involving purely medical points, arbitration might be more generally employed, saving immense legal costs, and indeed, I might say, the credit of our profession in the matter of cross evidence.

A WINDFALL FOR THE CARLISLE INFIRMARY.

The Carlisle Infirmary has received a cheque for nearly £2000, which must be regarded as unexpected, and in the light of a windfall. It took place in this way. More than a generation ago a lady died in Cumberland, who left the residue of her property to the infirmary. When the executors wound up her affairs it was found that there was only about £100 left, and an unknown sum to be probably paid to the Inland Revenue. As this was not claimed, it was invested in the funds. Years rolled by, during which executor after executor died, the matter being forgotten, and the sum increasing by way of compound interest to close on £2000. The Commissioners for the Reduction of the National Debt advertised the amount. This led to an inquiry, and representatives of the lady's executors were found, who claimed and received the money, and paid it over to the infirmary last week.

DEATHS OF NORTHERN PRACTITIONERS.

Dr. Valentine Hutchinson, a well-known surgeon in Bishop Auckland, died in that town last week, at the age of sixty-two. He had practised for about forty years, and had held various public offices. Dr. John Todd Macaulay also died in this city last week, at the early age of twenty-five. He was a member of a well-known and highly respected medical family here. His career thus cut short was one of much promise, as he was known to possess abilities in the profession above the average for one of his age and experience. He had likewise gained the good opinion of his medical brethren in this city, and he has died regretted by a great number of personal friends.

MUNIFICENT BEQUESTS BY A SOUTH SHIELDS GENTLEMAN.

Mr. R. Shortridge, a well-known county magistrate of Durham, died at his residence, Cleadon Meadows, South Shields, on the 11th of December. He has left over £8000 to various local and general charities, including the following amounts: Newcastle Infirmary, £2000; Ingham Infirmary, South Shields, £2000; South Shields Dispensary, £500; Deaf and Dumb Asylum, Newcastle, £500; Convalescent Home, Whitley, £500; and £1000 between the South Shields Sick and Indigent Asylum and the Blind Institution, Newcastle. Mr. Shortridge attained the great age of ninety-one years.

YELLOW FEVER IN A NEWCASTLE STEAMER.

The *Iolanthe*, of Newcastle, having arrived in Shields harbour last week from the West Coast of Africa, was boarded by the port sanitary officer, who found that six of her crew, including the boatswain, had died of yellow fever during the voyage; the mate was also attacked, but he recovered. Had this vessel arrived during the hot weather of the past season it might have caused much alarm, though at the present time the temperature on our north-east coast is such that yellow-fever could hardly exist.

THE COUNTY OF NORTHUMBERLAND AND FOOD ADULTERATION.

The reports of the public analyst for the past year have recently been published, and although the County of Northumberland as compared with other counties occupies a fairly favourable position, yet it is to be regretted that it shows an increase of nearly 8 per cent. in the number of adulterations found in articles submitted for analysis. The adulterations, however, would appear to be of the most innocent nature. The mixture used being not sand, alum, nor fetid fats, but water. In every case the adulteration was found either in milk or spirits; thus, in fifty-three samples of milk tested thirteen were found impure. In the case of a complex fluid like milk, however, we do notlike to hear of any admixture of water, fearing that the adulterator may not be scrupulous as to the quality of the water he uses, but rather consider the quantity it will carry without risk of discovery.

Newcastle-on-Tyne, Dec. 31, 1884.

WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL.—On the 23rd ult. Mr. Vincent Jackson, honorary consulting surgeon at this institution, handed to the weekly board a cheque for £100, which he had received as subscriptions from a few ladies and gentlemen in the town towards the cost of a new building for the treatment of the surgical diseases of women.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS.

At a recent meeting of the Council, a motion proposed by Prof. Cameron, Vice-President of the College, to the effect that women should be admitted to all the examinations of this College, was adopted, the voting being 7 for and 4 against the resolution. The matter will, it is probable, come before the Fellows very shortly. No doubt there is a difference of opinion as to the desirability of admitting ladies to practise medicine and surgery, but, if women will be qualified, it is better that they should obtain their diplomas from an institution like the Royal College of Surgeons in Ireland than from some other licensing body where only a minimum of professional knowledge is expected.

PRESENTATION ADDRESS AND TESTIMONIAL TO DR. DENHAM OF DUBLIN.

This esteemed member of the obstetric branch of the profession—a leading practitioner for many years in Dublin having intimated his intention of retiring from practice, it has been resolved by numerous friends to present him with an address and testimonial, to show the respect and esteem in which he is held. Dr. Denham formerly held the responsible post of Master to the Rotundo Lying-in Hospital, and is an ex-President of the Royal College of Surgeons in Ireland. In consequence of failing health he some time since retired from the Council of his College, having been a member of it for many years. I am confident that the many friends of Dr. Denham will regard it as a duty and a pleasure in cordially co-operating to carry out the proposed address and testimonial.

ENNIS DISTRICT LUNATIC ASYLUM.

Dr. Daxon, late medical superintendent of this asylum, having retired in consequence of failing health, has been replaced by Dr. Richard Philips Gelston, who for the past fifteen years has occupied the post of assistant medical officer at Clonmel Asylum. The appointment is worth £400 per annum, with the usual emoluments, and an increase of £20 every third year until the salary reaches £500.

DUBLIN ORTHOPÆDIC HOSPITAL.

From the report which was adopted at the recent annual meeting in connexion with this institution, it appears that there are now thirty-one beds available, which the committee hope to increase to forty as soon as funds will permit. Several speakers referred to the advisability of amalgamation between the institution and the National Orthopædic and Children's Hospital, and the Lord Mayor, who presided, was requested to inform the Corporation that for the last four years they had been most anxious for a grant. It has, however, recently been stated that the National Orthopædic Hospital is about to amalgamate with another Dublin institution.

MATER HOSPITAL FOR WOMEN AND CHILDREN.

This admirable institution having become involved in a debt of some £400, which impaired its efficiency, a bazaar was recently in order to remove this liability. Since its foundation, more than ten years since, the hospital has been of incalculable benefit, and it is to be hoped the bazaar in aid of funds may have been as successful as its promoters could desire.

PARIS.

(From our Paris Correspondent.)

COCAINE.

The medical press is full of cocaine just now; and most of the writers who have referred to it seem to speak of it as a new discovery, which they attribute to Dr. Koller. This is simply giving the young Vienna physician more credit than he ever claimed for himself, and all that can be accorded to him (and that is a great deal) is his being the first who applied cocaine to ophthalmic practice, for its anæsthetic properties had long been known. Other writers, in giving the history of coca and its derivatives, and of their therapeutical applications, have entirely ignored what had been done in France with these drugs. Dr. Charles Fauvel, the celebrated laryngologist of Paris, has, to my own knowledge, employed a concentrated extract of coca since 1869 at his clinique as a local anæsthetic in naso-pharyngo-laryngeal affections. In 1877 Dr. Scaglia, Dr. Fauvel's chef de clinique, published a report in the *Gazette des Hôpitaux*, in which the anæsthetic property of coca and its efficacy in painful affections of the throat was brought to the notice of the profession. In 1878 Dr. Coupard, another of Dr. Fauvel's chefs de clinique, published in the *Tribune Médicale* a report entitled "La Coca dans les Affections douleureuses du Pharynx et du Larynx," in which a strong alcoholic extract from the leaves of the coca is stated to have been employed for painting the throat. In 1880 Dr. Coupard, in conjunction with Dr. Bordereau, undertook a series of experiments with a hydrochlorate of cocaine, which was obtained from the plant under their immediate supervision, at which the local anæsthetic and mydriatic effects were clearly established; but, for some unaccountable reason, this discovery did not receive further attention, either in this country or elsewhere, until the announcement made by Dr. Koller at the Ophthalmological Congress held at Heidelberg in September last. The experiments of Dr. Coupard were repeated, and verified in 1882 by Dr. Laborde, the well-known experimental physiologist, who, in addition, proved that cocaine possessed general anæsthetic properties as well. To this day Dr. Fauvel employs a solution of coca for painting the throat in the various forms of painful angina, which he prefers to cocaine, as, however useful the latter may be in ocular or other therapeutics, he considers it inapplicable to affections of the throat, owing to its toxic properties. Moreover, cocaine is much more expensive and less manageable than coca, though Dr. Fauvel would admit that when the former is employed with caution it is far superior to coca for laryngoscopic examinations, for which he uses a 5 per cent. solution of the hydrochlorate of cocaine. This he much prefers to the old method of painting the pharynx with a saturated solution of the bromide of potassium, or to the German method of touching the vocal cords alternately with pure chloroform and a concentrated solution of morphine for twelve consecutive hours, in order to produce insensibility of the parts prior to operation. Besides the local employment of coca, Dr. Fauvel prescribes it as a general tonic and as a stimulant to the cerebro-spinal system in the form of infusion, pastilles, and wine; and he has observed that even when administered by the stomach, the tonic action of coca is so marked in cases of atony of the muscles of the larynx and relaxation of the vocal cords, that Dr. Fauvel has given it the name of "tenseur des cordes," and it has long been a popular remedy among singers, public speakers, &c.

DEATH OF M. J. B. GEORGE.

It is with regret I have to report the death of Mr. J. B. George, the well-known dentist of Paris, which took place on December 22nd, when he had just completed his fifty-eighth year. Mr. George had been practicising as a dentist for nearly forty years, during which time he acquired a great reputation as a skilful operator, and had one of the best practices among the *élite* of Parisian society. His son, who has just attained his majority, and has served his apprenticeship under his father, has succeeded to the practice, but being still rather young, he is ably seconded by Dr. Thomas, a renowned dentist of New York, who formerly worked with his father. Dr. Thomas had returned to New York, but on hearing of the serious illness of Mr. George he came back to Paris to give a helping hand to the son.

Paris, Dec. 30th.

MANCHESTER ROYAL INFIRMARY.—At a meeting of the Board of Management of this institution on the 29th ult., attention was called to the position taken up by the Health Committee of the Corporation in regard to payments for patients in Monsall Hospital. The Health Committee, believing that patients sent by them to the hospital are kept longer than is necessary, have refused to pay in full the accounts for the last two quarters. The deductions they make amount to about £500. The infirmary board, insisting that in such a matter they must be guided by their medical staff, passed a resolution expressing surprise at the action of the Health Committee, and calling upon them at once to pay what is due.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the examinations for Medical and Surgical Degrees held during Michaelmas term, the following candidates were approved:—

THIRD EXAMINATION FOR THE DEGREE OF M.B.

PART I.—Ds. Clarke, Caius; Griffith, Down.; Mag. Habershon, Trin.; Mag. Haviland, Joh.; Ds. Hillier, Caius; Ds. Musgrave, Magd.; Ds. Piggott, Emman.; Ds. Reid, Cav.; Ds. Ritchie, Trin.; Ds. Sherrington, Caius; Ds. Stericker, Clare; Turner; Weston, Caius.

PART II.—Ds. Emerson, Clare; Griffith, Down.; Mag. Habershon, Trin.; Ds. Knaggs, Caius; Mag. Lyon, Emman.; Ds. Rutherfoord, Caius; Ds. Sherrington, Caius; Mag. Styan, Trin.; Ds. Trott, Caius; Turner; Ds. White-Cooper, Trin.

DEGREE OF B.S.

Ds. Piggott, Emmanuel; Shaw, Sidney; Mag. Street, Trinity; Ds. Ritchie, Trinity.

UNIVERSITY OF DUBLIN.—The following degrees were conferred at the winter commencements:—

BACHELOR IN SURGERY.—Baptist Gamble Frith, William Hallaran, Francis John Harpur, G. Kiddle, Telford Smith.

BACHELOR IN MEDICINE.—Alexander James Boyd, John Blacker Buchanan, Thomas N. Flood, Baptist Gamble Frith, Richard Whately Gilmore, William Hallaran, G. Kiddle, Francis Joseph George King, William Richardson Rice, Rowland Hill Scovell, John James Watson.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At the December examinations the following, having passed their final examinations for the Letters Testimonial, were admitted Licentiates of the College:

Alfred E. T. Barcroft, Patrick J. Barry, Anthony L. Blake, Henry Breen, Edward Browne, Allan Butler, William J. Darby, Vesey Davoren, Ignatius P. Doyle, John Emerson, John Esmond, Henry J. Flanagan, William F. Fullam, Joseph W. Gallagher, John J. Gaynor, George E. Greene, James Halpin, Ernest Howe, Francis Knox Blake, John E. Lanegan, William H. Suggar, Anthony J. Luther, Joseph D. McFeely, John McGuinness, Herbert C. Mooney, John L. Moore, Bernard Murray, James Normile, Marshall P. O'Donovan, Paul A. Peile, James E. Riddle, Alfred J. S. Roe, John C. Sellers, Graves Stoker, Henry Stoker, Davis D. Tate, Robert C. Thacker, Richard H. Vereker.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 23rd ult.:—

Bates, George Tweedie, University College.
Caswell, George William, University College.
Fowler, Walter, Guy's Hospital.
Hildyard, Robert Loxham, King's College.
Jones-Humphreys, Yarry Meyrick, Guy's Hospital and Liverpool Royal Infirmary.
Leggatt, Gerard Stedman, St. Bartholomew's Hospital.
Lavies, Harry Brandreth, King's College.
Monk, Henry George Hawkins, King's College.
Selway, Leonard, Guy's Hospital.
Stedman, Frederick Osmund, Charing-cross Hospital.
Stubbs, Percy Bedford Travers, St. Bartholomew's Hospital.

The following gentlemen also on the same day passed the Primary Professional Examination:—

George Taylor Gifford, King's College; Samuel Edwin Lambert Smith, General Hospital, Birmingham.

DR. PALEY, of Peterborough, fractured one of his thighs on the 26th ult., through a fall in the hunting-field.

THE Queen has presented to the funds of the Booksellers' Provident Institution a donation of £20.

ST. ANDREWS UNIVERSITY.—The Chair of Chemistry, vacant by the retirement of Professor Heddle, has been filled by the appointment of Thomas Purdie, Ph.D., B.Sc. Lond.

VACCINATION GRANT.—Mr. R. L. Shone, M.R.C.S. and L.S.A., has received the Government grant for successful vaccination in the Mortlake district of the Richmond Union.

THE DEATH OF A GOODS GUARD.—An inquest was held at New Barnet on the 30th ult. on the body of Joseph Nichols, a guard, of Bingfield-street, Caledonian-road. The deceased was the only occupant of a third-class compartment in a train proceeding on Saturday from King's-cross to Peterborough, his duty being to work another train back. The train stopped at Hitchin, and Nichols was then missed. His body, fearfully mutilated, was found on Sunday morning in Barnet Tunnel. The supposition is that he fell out of the train and was run over. A verdict of accidental death was returned.

QUEEN CHARLOTTE'S HOSPITAL.—A petition has been addressed to Her Majesty in Council, praying that a charter of incorporation may be granted to Queen Charlotte's Lying-in Hospital. Having been referred to a Committee of the Lords of the Council, the petition will be taken into consideration on the 31st inst.

ASSOCIATION OF PUBLIC SANITARY INSPECTORS.—At the meeting to be held to-day (Saturday), at 6 o'clock, at 1, Adam-street, Adelphi, Mr. Edward C. Robins, F.S.A., will deliver an address on "The Growing Importance and Responsibility of Public Sanitary Inspectors explained, and their Relative Improvement in Education, Position, and Emoluments considered."

ON the 30th ult. an inquest was held at Chester on the body of Maria Burns, aged forty-three years. She attempted to light a paraffin lamp by thrusting the top into burning coals. The top came off, and her dress caught fire. Paralysed and unable to cry for assistance, she was found in a dreadful condition sitting down with her burning clothes about her. She died shortly afterwards. A verdict of accidental death was returned.

THE WORKING MEN'S CONVALESCENT HOME.—The first annual report of the Committee of Management of Morley House Convalescent Home at St. Margaret's Bay, near Dover, states that at the close of the financial year there was a balance after payment of all expenses of £63. A loan of £2000, obtained to effect the purchase of the freehold of the building and seven adjacent acres of land, however, still remains to be paid off. The subscriptions and donations during the past year amounted to £1610, and the payments by patients to £175.

THE RICHMOND WATER-SUPPLY.—After an expenditure of some thousands of pounds, the Richmond Select Vestry, upon the recommendation of the Water-supply Committee, have resolved to discontinue the deep boring of their well. In their report the committee state that it is not now clear to them that as the boring progresses there is a satisfactory increase in the yield of water; that the difficulty of boring and the consequent expense increase with every foot bored; that the opinion of Professor Judd, one of the highest authorities in the kingdom, only indicating a possibility but not a probability of finding water is not encouraging; and while the committee would gladly continue boring in the interests of science, they feel bound in the interests of the ratepayers not to continue unless there is a reasonable and well-supported prospect of ultimate success. At the last ordinary meeting of the Vestry, the chairman (Major Bull) stated that it might be possible that some learned society or the Government might be induced to grant money to continue the boring operations at the well in the interests of science. It had attracted a vast amount of attention in this country and on the Continent and throughout the world, but more particularly among French scientists, who had discussed it at their meetings. The present depth of boring is 1439 feet.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ACKERY, JOHN, M.R.C.S., L.D.S., has been appointed Assistant Dental Surgeon to St. Bartholomew's Hospital.

ADDENBROOKE, E. H., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the District of Kidderminster.

ALLEN, Mr. ALFRED HENRY, has been reappointed Public Analyst for the Borough of Wakefield.

BEATTIE, HENRY, L.R.C.P.L., M.R.C.S., has been appointed Medical Officer for the South District of St. George's in the East, vice Pritchard, deceased.

BUCHANAN, JOHN, M.B. & C.M.Glas., has been appointed Junior House-Surgeon to the Royal Albert Edward Infirmary, Wigan, Lancashire, vice A. B. Liptrot, resigned.

BUCKBY, ROBERT GREVILLE, L.R.C.P.Ed., L.R.S.I., has been appointed Medical Officer for the Bulwell District of the Basford Union.

BUSH, J. PAUL, M.R.C.S., has been appointed Surgeon to the Bristol Police Force, vice F. R. Cross, M.B., F.R.C.S., resigned.

COLLINS, WILLIAM JOB, M.D., B.S., B.Sc.Lond., F.R.C.S.Eng., has been appointed Ophthalmic Surgeon to the North-West London Hospital.

DACRE, JOHN, L.R.C.P.Lond., M.R.C.S., has been appointed House Physician to the Bristol Royal Infirmary, vice J. Fenton Evans M.B., promoted.

ELLIOTT, W. T., L.D.S.Ed. & Dub., F.C.S., has been appointed Assistant Dental Surgeon to the Birmingham Dental Hospital.

EVANS, A. FENTON, M.B., C.M., has been appointed House-Surgeon and Senior Resident Medical Officer to the Bristol Royal Infirmary, vice J. Paul Bush, resigned.

EVANS, T. ANEURIN, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer of Health for the Flint Urban Sanitary District, vice Jones, deceased.

FLETCHER, WILFRED W. E., M.B.Cantab., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Ormskirk Rural Sanitary District, vice the Poor-law District Medical Officers, whose appointments have expired.

HAWKINS, ALEXANDER F., L.R.C.P.Lond., M.R.C.S., has been elected Honorary Obstetric Officer to the Queen's Hospital, Birmingham.

HAWKINS, C. F., M.R.C.S., L.S.A.Lond., has been appointed Public Vaccinator for the District of Clifton, Bristol, vice L. Matthews Griffiths, M.R.C.S., resigned.

HAWKINS, FRANCIS H., M.B., C.M., has been appointed House-Surgeon to the Victoria Hospital for Sick Children, Queen's-road, Chelsea, S.W.

HUTCHINSON, JONATHAN, jun., M.R.C.S., has been appointed Surgical Registrar to the London Hospital.

JAMES, J. LEWIS, M.D., has been appointed Attending Medical Officer to the South London Medical Aid Institute, vice E. O. Day, resigned.

LEFFINGWELL, Mr. EDWARD, has been appointed Demonstrator to the Dental Hospital of London.

LIPSCOMB, A. BAILEY, M.R.C.S., L.R.C.P.Ed., has been appointed House-Surgeon to the Liverpool Eye and Ear Infirmary.

MARSHALL, ALFRED S., M.R.C.S., L.R.C.P.Ed., has been appointed Assistant Dental Surgeon to St. Bartholomew's Hospital.

MAYFIELD, WILLIAM ELLIS, L.R.C.P.Ed., L.R.C.S.Ed., has been re-appointed Medical Officer of Health for the Pudsey Urban Sanitary District.

PEARD, JOHN, F.R.C.S.Eng., has been appointed Surgeon to the Miller Memorial Hospital, Greenwich, S.E.

PETRIE, HARRY, M.R.C.S., has been appointed Medical Officer for the Preston District of the Basford Union.

POWELL, A. WORSLEY, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Assistant Colonial Surgeon and Medical Officer to the Mount Gambier Hospital, South Australia.

SHAW, JOHN A., M.R.C.S., L.S.A.Lond., has been reappointed Registrar to the Victoria Hospital for Children, S.W.

THURSTON, HUGH C., M.R.C.S., L.R.C.P.Lond., has been appointed Assistant Resident Medical Officer and Pathologist to the Bristol Royal Infirmary, vice J. Daere, promoted.

TURNBULL, HAROLD A., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Second District of the Eastbourne Union, vice Billing.

WHITEHOUSE, BENJ. ARTHUR, M.D.L., M.R.C.S., S.S.Cert.Camb., has been appointed Medical Officer of Health for the Nottingham Urban Sanitary District, vice Seaton, resigned.

Births, Marriages, and Deaths.

BIRTHS.

DAY.—On the 4th ult., at Dundas Villa, Redcar, Yorkshire, the wife of William A. Day, M.R.C.S., of a daughter.

HASKELL.—On the 27th ult., at Oldfield House, New Cross, S.E., the wife of Morgan Dockrell, B.A., M.B.Dub., of a daughter.

LAWLEY.—On the 29th ult., at The Limes, Woking, the wife of T. Cawley Lawley, M.D., of a daughter.

MAYES.—On the 22nd ult., at Clarges-street, Mayfair, the wife of Thomas Crawford Hayes, M.D., of a daughter.

PARKER.—On the 18th ult., at British Burmah, the wife of T. Franklin Parker, M.D., Health Officer, Rangoon, of a daughter.

PENNY.—On the 27th ult., at Pinxton, Derbyshire, the wife of Edward Penny, M.D., of a son.

STOCKER.—On the 20th ult., at Weston House, Richmond-gardens, Shepherd's-bush, the wife of Chas. J. Stocker, L.R.C.P.L., of a daughter.

WATKINS.—On Nov. 14th, at Boshof, Orange Free State, South Africa, the wife of Harold Fuller Watkins, M.B. C.M.Ed., of a daughter.

WELLS.—On the 29th ult., at College-crescent, Belsize-park, N.W., the wife of Chas. Wells, M.D., M.R.C.S., &c., of a son.

MARRIAGES.

GILMOUR—GILMOUR.—On the 23rd ult., at the Alexandra Hotel, Glasgow, Hugh Arthur, M.D., Airdrie, to Elizabeth Gilmour, only daughter of James Mennel, Esq., Muirhead, Shotts.

ASHWORTH—SMYTHE.—On the 23rd ult., at the Parish Church, Hunstanton, J. Henry Ashworth, F.F.P.S. Glas. and M.R.C.P. Ed., of Hunstanton, Essex, to Kate, younger daughter of the late Henry Smythe, M.D., of King's Lynn.

BARKER—BARKER.—On the 18th ult., at All Saints', Oldham, Hants, Charles Wilmot Barker, M.D., M.R.C.P., son of the late Harry Wilmot Barker, Esq., Barrister-at-law, to Louisa Frances Agnes Barker.

DEATHS.

DODD.—On the 28th ult., at 10, Carlisle Parade, Hastings, Mary, the wife of Russell Dodd, M.R.C.S., L.R.C.P.Lond., of 24, Montagu-street, Portman-square, W.

LLOYD, the 28th ult., at Llanfabon, John Leigh, J.P., F.R.C.S., aged 58.

VAUGHAN.—On the 17th ult., at his residence, Llanvair House, Builth, John Vaughan, late Surgeon-Major Bombay Army, in his 57th year.

WRIGHT.—On the 28th ult., after a short illness, John Freeman Wright, M.R.C.S., of Meridian-road, Clifton, and late of Seymour-street, London, aged 66.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, January 5.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. T. Lauder Brunton: Digestive Disorders, their consequences and Treatment (Lettsomian Lecture).

Tuesday, January 6.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 1 P.M., and on Fridays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Tyndall: The Sources of Electricity.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—4 P.M. Quarterly General Meeting.—Mr. Lennox Browne: Inebriety as affecting the Vocal and Respiratory Organs.—Communication from Dr. Joseph Parrish, President of the American Association for the Cure of Inebriety.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Lane; Fracture of the First Rib alone, and its Causation.—Mr. Godlee: Extensive Fracture of the Skull in an Infant, with Effusion of Serous Fluid.—Mr. Pepper: A Case of Malignant Disease of the Spermatic Cord.—Dr. Norman Moore: (1) Congenital Disease of Heart; (2) Hæmorrhage into the Substance of the Liver (card).—Mr. Lockwood: Rudimentary Abdominal Ribs (card).—Dr. Silcock: Tubercular Disease of the Epididymis (card).—Dr. Charlewood Turner: (1) Congenital Stenosis of Œsophagus; (2) Aneurysm of the Aorta opening into the Œsophagus (card); (3) Aneurysm of Sinus of Valsalva, with Abnormal Coronary Arteries.—Dr. Herringham: Two Specimens of Calcareous Change in the Spinal Membrane (card).—Mr. Poland: Synostosis of Foot (card).—9.30 P.M. Election of Officers and Council.

Wednesday, January 7.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour. Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Thursday, January 8.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Tyndall: The Sources of Electricity.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Living and Card Specimens. 8.30 P.M. Mr. F. R. Cross: (1) Case of Congenital Iridæremia; (2) Cystic Tumour of Iris; (3) Cholesterine Crystals in the Vitreous.—Mr. E. Nettleship: Total Detachment of Retina of long Standing, with Retention of some Sight.—Mr. W. A. Brailey: Irido-cyclitis, with Hyphæma and enormously deep anterior chamber (sequel of case shown at the last meeting).—Mr. G. Hartridge: Opaque Nerve Fibres.—Mr. W. H. Jessop: Tubercle Bacilli in Blood Serum (cultivated), and in Iris of Rabbit (after inoculation).—Ophthalmoscopes will be exhibited by Messrs. Couper, Gunn, Morton, G. L. Johnson, and others—Mr. W. H. Jessop: On the Cocainised Eye; Discussion on the Action of Cocaine (adjourned from last meeting).—Mr. W. A. Brailey: On the Condition of the Ciliary Nerves in various Eye Diseases, with microscopical specimens.—Mr. J. Couper: An Improved Ophthalmoscope.—Mr. A. S. Morton: An Improved Students' Ophthalmoscope.—Report of the Committee on the Influence of the Vapours of Bisulphide of Carbon and of Chloride of Sulphur on the Vision and General Health.

Friday, January 9.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Annual General Meeting for the Election of Officers and Council.—Dr. Hale White: Case illustrating Lesions of the Frontal Lobe, with very few symptoms.—Dr. Pringle: A Case of Recurrent Hæmatemesis, with Urticaria.—Mr. B. Roth: A Case of Hydrocephalus in a Boy aged Sixteen, who has never walked (living specimen).

Saturday, January 10.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

OVARIOTOMY.

AT a recent meeting of the Surgical Section of the Academy of Medicine in Ireland, a paper on Ovariotomy, by Mr. William Thomson, was the subject of considerable discussion. There were two points principally under consideration—namely, the question of drainage, and of specialism as regarded the operation. It was generally conceded that hospital surgeons accustomed to emergencies of all kinds were perfectly competent to perform ovariotomy, as compared with obstetric surgeons, and that there was no valid reason why the latter should have a monopoly of the operation in question. Drainage-tubes, it was believed, might usually be dispensed with, although occasions arose when their use might be of advantage. Dr. Lombe Atthill, ex-Master of the Rotunda Lying-In Hospital, who has had the most extensive experience of ovariotomy of any surgeon in Ireland, was of the opinion that there was a better chance of recovery when the operation was undertaken in the early stages of ovarian disease.

Z. Y. X.—We do not know of any society of the kind mentioned. The instruments are very inexpensive.

"A NEW FORM OF DILATOR FOR STRICTURE OF THE URETHRA."

To the Editor of THE LANCET.

SIR,—The dilator which Mr. Walsham describes in your issue of Dec. 20th is identical in principle and construction with one made for me by Messrs. Meyer and Meltzer, and which was the result of months of careful and costly experiments. It was exhibited at the Obstetrical Society of London on June 4th, 1884; and I stated that although it had been invented for dilating the uterus, it might be used for the urethra. I have not found it necessary to carry the indiarubber sheath over the whole instrument, but I stated at the meeting that this might be done if thought necessary. The credit of inventing this excellent dilator is more due to Mr. Meyer than myself; and, I am sure, Mr. Walsham would not wish to deprive him of any meed or material advantage which has been so laboriously earned.—Yours faithfully,

Upper Wimpole-street, W., Dec. 24th, 1884. JAMES H. AVELING.

Mr. Geo. Padley.—The insertion of the note would probably give rise to a controversy for which at present we have not space.

Novice.—1. Yes, price 2*s.* each.—2. No.—3. No instructions would be necessary.

THE CASSAN FUND.

To the Editor of THE LANCET.

SIR,—Will you allow me to acknowledge through your columns the following additional donations received towards this fund:—The Lincoln Medical Society, £10; Dr. O'Connor, Gainsborough, £1 1*s.*

I am, Sir, yours faithfully,

H. F. LANCASTER, M.D.

275, Lewisham High-road, S.E., Dec. 31st, 1884.

THE EXCELSIOR GYMNASIUM.

Dr. J. Sawyer and others.—The address of the inventors of the above-named ingenious apparatus was inadvertently omitted from the description we gave of it last week. It is as follows:—Messrs. Chadborn and Caldwell, New York, and 223, Upper Thames-street, London.

Opium.—There is as yet no such establishment in England, nor have we heard of any in Germany. The demand for an institution of the kind is not, we trust, sufficient to render it necessary.

THE P. AND O. COMPANY'S MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—I beg to forward for your perusal an exact copy of a circular recently issued by the P. and O. Steam Navigation Company in reference to the conduct of the surgeons of their steamers.

The first paragraph—viz., prohibiting surgeons from claiming fees from sick passengers—I have nothing to find fault with. We are paid a fixed salary by the Company for our services, which are supposed to include professional attendance on all sick people on board, whether crew or passengers.

The second paragraph, however, states: "A passenger is not only entitled to medical attendance and medicines whilst he is on board, but he is entitled to ask for and to obtain a copy of the prescription for any medicine which the surgeon has administered to him." In other words, a passenger is not only entitled to medical attendance while on board ship, but can, by means of a prescription compulsorily exacted, render himself independent of further advice when he goes on shore.

The third paragraph is far more arbitrary. I had hitherto believed that medicines were supplied by the Company to their ships for the exclusive use of the surgeons in the treatment of patients under their charge, but it would appear that we are expected to perform in addition the role of pharmaceutical chemist, and blindly dispense a prescription for any passenger without having previously ascertained that it be suitable to the present state of the patient, except only that we are considerately told in an added clause that "the surgeon would not be justified in administering in these circumstances an unusual dose, or in making up a prescription to a patient who was very ill, without in the first instance satisfying himself that the medicine was suitable to the circumstances of the case." Or, in plain language, we are seriously informed that we are not justified in following out their instructions so literally as to run the risk of poisoning a patient, and that in cases of serious illness we are allowed to satisfy ourselves of the suitability of the medicine to the circumstances of the case.

It would surely be no great hardship for those who desired to continue a certain course of treatment to bring with them a supply of medicine sufficient for their use during the voyage, or, failing this, they might easily procure the same at one of the numerous ports touched at by the Company's mail steamers, in all of which are chemists well qualified to dispense English prescriptions.

The responsibility for this circular, however, does not rest entirely with the managing directors of the Company, as they possess the services of a medical inspector, who is in attendance weekly at the head office of the Company in London, and without whose knowledge and approval no such document would have been issued.

I am, Sir, yours truly,

A P. AND O. SURGEON.

"No. 140." "MEDICAL FEES."

"Peninsular and Oriental Steam Navigation Company's Offices,
124, Leadenhall-street, London, E.C., 1st Nov., 1884.

"*To the Commander of the SS.* '

"Dear Sir,—Complaints have recently been made by passengers that surgeons of the Company's ships have applied to them for fees, and we have found to our great regret that these complaints have been to a large extent justified. As the surgeons against whom the complaints were laid alleged special circumstances in the respective cases, we have now to intimate that under no circumstances whatever is a surgeon allowed to ask for a fee.

"A passenger is not only entitled to medical attendance and medicines whilst he is on board, but he is entitled to ask for and to obtain a copy of the prescription for any medicine which the surgeon has administered to him.

"It does and must happen that passengers in delicate health, or subject to occasional attacks of illness, will desire to obtain medicines which have been prescribed for them by previous medical advisers. It is our wish that every facility should be given by the surgeon to gratify this natural desire, and surgeons are requested to dispense any prescription which a passenger may ask them to make up if they have the medicines required, so long as the prescription does not direct the employment of any powerful medicine in an unusual dose, and the passenger is not seriously ill.

"The surgeon would not be justified in administering in these circumstances an unusual dose, or in making up a prescription to a patient who was very ill, without in the first instance satisfying himself that the medicine was suitable to the circumstances of the case.

"We have pleasure in testifying that complaints of the kind referred to have been made against only a small minority of the surgeons, and we are satisfied that as a rule the surgeons of the fleet are gentlemen whose habits of tact and forbearance are sufficient to ensure in all cases a feeling of cordiality between themselves and their patients; and this is an additional reason why we shall feel it incumbent on us to deal severely with surgeons who, under the influence of short-sighted motives, come unpleasantly into collision with the passengers of whom they have charge. You will be good enough to obtain the signature of the surgeon of your ship to this circular, as evidence that he has read and noted its contents, and you will adopt the same course when a fresh surgeon joins, in order that none may plead ignorance of our wishes.

"We are, Dear Sir, yours faithfully,

"THOS. SUTHERLAND (for the Managing Directors.)"

WEEKLY DINNERS FOR POOR CHILDREN.

THE London Cottage Mission have issued an appeal, announcing that they have commenced their Irish stew dinners to the poor children in the East of London, but that the funds of the Mission being so low, and there being so many pressing liabilities to meet in connexion with the Summer Home and general mission works, the dinners must cease unless special contributions are obtained. Whatever differences of opinion may be held as to the relative merits of penny dinners, half-penny dinners, and free dinners, of their absolute utility there can be none. The movement is a good one, and deserves extensive support. Subscriptions and donations will be thankfully received and acknowledged by Miss F. Napton, the Lady Superintendent, 304, Burdett-road, Limehouse, E.; the London and South-Western Bank, 7, Fenchurch-street, E.C.; and by Walter Austin, Managing Director, 44, Finsbury-pavement, E.C.

Medicus.—1. Our correspondent cannot practise legally on this diploma.—2. He is not likely to be convicted for using the title attaching to his degree, if obtained after a *bona fide* examination.—3. He cannot obtain an English licence without an examination.

M.R.C.S.Eng.—No. The case is a hard one; but such is the law. The examination covered all branches of practice—surgery, medicine, and midwifery; but the diploma is a qualification only in surgery.

ELECTION TO HOSPITAL APPOINTMENTS.

To the Editor of THE LANCET.

SIR,—On behalf of the large number of applicants which there is at the present time for any resident hospital appointment, I would ask you to draw your attention to the fact that the authorities of some hospitals seem quite regardless of the expense to which they put the candidates for such posts. Let me tell how matters are managed when the committee of a large and well known hospital in the Midlands advertises a vacant appointment. Each candidate is supplied with a list of the members of the committee, some forty or fifty in number. To each of these he must send a copy of testimonials. He further learns with dismay that he is expected (of course, it is optional, but a man stands a poor chance of success who neglects it) to interview personally and individually the men whose names appear on this list. The anxious candidate then sets out on his travels, starting perhaps from London, Edinburgh, or Dublin, and spends several days in seeing the members of the committee, on some of whom he calls three, four, or even more times before he obtains an audience. He is in a few cases received with attention, and interest is shown in the election. In most cases he is treated with curtness little short of rudeness. He usually finds that little interest is manifested in the affair by those whom he has come perhaps hundreds of miles to see. They say (and with truth) that "they leave these things in the hands of the visiting staff." His canvass ended, the candidate returns home, only to make another journey a few days later to appear at the election. Here the candidates are told that as their presence, though perhaps deemed necessary, was not actually requested, no travelling expenses can be allowed. The successful candidate may think lightly of the pounds he has expended in obtaining his appointment—no small percentage, perhaps, of his next year's salary—but the rejected men look regretfully at the total of their travelling and hotel expenses for the last few weeks, and think hard things of those who instituted so wasteful a system of election.

I could give other instances of men called from a distance to interview committees, sometimes twice in connexion with the same appointment, when "no expenses were allowed." I have, moreover, noticed that in those cases where travelling expenses of selected candidates are allowed only three or four are usually selected for a personal interview with the electing committee, but that where these expenses are borne by the candidates the committee is by no means niggardly in the number of men selected or the number of times their presence is required. Thus, much more money is spent by the candidates in an appointment of this sort than it would have been necessary for the hospital committee to expend on a properly conducted election.

As there are two sides to a bargain, and the hospital is as much a party to the election as the person elected, and certainly derives greater benefit from it than the unsuccessful candidates who are made to bear the greater part of the expenses connected with it.

I should be glad, Sir, if you would through the columns of your journal urge the payment of travelling expenses to selected candidates for appointments as I have mentioned, and discountenance the system in any form as being either unfair or useless.

I am, Sir, yours obediently,

December 27th, 1884. AN UNSUCCESSFUL CANDIDATE.

ARMY PROMOTION.

We observe that our contemporary the *Army and Navy Gazette* is of opinion that we should inform him "by whose hand" a verbal correction was made in the questions for promotion of surgeons-major which were published in THE LANCET. We cannot gratify his curiosity, as we printed them exactly as we received them, through the courtesy of the Director-General, in reply to an application which we made for them, as we considered they would be interesting to many of our readers.

POISONOUS CONFECTIONERY.

AT a recent meeting of the New York Health Board, Dr. Cyrus Edison presented his report upon the adulteration of candies. The factories and goods of sixty-four firms engaged in the manufacture of sugar confectionery in New York were inspected. Thirteen of these firms were found to be using chrome yellow (chromate of lead) for imparting a yellow colour to their candies. Five of the thirteen were using chrome green (chromate of lead and ferrocyanide of iron), red lead (red oxide of lead), vermilion (bisulpheret of mercury), and Prussian blue (ferrocyanide of iron). Three were using burnt umber, for imparting a chocolate colour; one was using fuschine (an aniline contaminated with arsenic), for imparting a red colour. The sugar confectionery coloured with poisonous pigments in the possession of manufacturers was seized and destroyed.

Enquirer.—Absolute perfection in any human work is not to be expected. The query propounded in the last part of our correspondent's letter must be answered in the affirmative.

Idem.—There is no invariable rule. It is right to ascertain the custom of the place, and to act accordingly.

Mr. F. N. Williams.—The question is too vague, but appears to be one that ought to be put to a solicitor.

A Constant Reader.—40, Margaret-street, Cavendish-square, W.

"UNSOUND MEAT."

To the Editor of THE LANCET.

SIR,—In your issue of the 20th ult., Dr. Henry E. Armstrong says that the medical officer of health, and not the veterinary surgeon, is the proper authority on the fitness of flesh for the food of man. He also asserts that the diagnosis of the veterinary surgeon as an expert on the diseases of quadrupeds should be accepted by a medical officer as a basis on which to arrive at a proper conclusion, but nothing more. In due deference to Dr. Armstrong I beg to assert that a veterinary surgeon and not a medical officer is the proper authority as to the fitness of flesh for human food. Surely, if a veterinary surgeon is to be called in as an expert to inform the medical officer as to the disease the animal has been suffering from, he (the veterinary surgeon) must be the fit and proper person to form a correct opinion as to whether the flesh is fit for food or not. In support of my views, I maintain that medical officers know little or nothing about the diseases and post-mortem appearances of quadrupeds, or why call in a veterinary surgeon to assist them, to arrive at a proper conclusion? Perhaps Dr. Armstrong has not forgotten the very serious outbreak of anthrax in cows, which occurred in this city a few years ago? If he had then been conversant with the post-mortem appearances of that fatal disease, he would never have made the serious mistake he then did of passing the flesh as fit for food; that anyone knowing the disease from which they suffered would never dream of doing; at least no veterinary surgeon would. It will be interesting to the curious to know that it was not until a veterinary surgeon pointed out to him his serious mistake that he fully realised the situation. And I have no doubt the curious will be still more interested to know how hastily he retreated to secure, if possible, those portions of flesh not disposed of as unfit for food. For Dr. Armstrong's benefit, I beg to say that the flesh of cows, if killed in the earlier stages of parturient apoplexy, is fit for food. And, in my humble opinion, it is a great sin that such flesh should be destroyed as unfit for food, as it often is by the medical officer. I have more than once brought joints home for the use of my family that had been condemned. In conclusion, I beg to ask Dr. Armstrong or any member of the medical profession in which part of their curriculum are they taught the diseases and post-mortem appearances of disease in quadrupeds. And how often do they attend slaughter-houses to inspect carcasses in health and disease.

I am, Sir, yours obediently,

Newcastle-on-Tyne, Dec. 27th, 1884. GEORGE ELPHICK.

To the Editor of THE LANCET.

SIR,—If one more argument were required to prove that meat inspection should be in the hands of the veterinary surgeon, Dr. Henry Armstrong has supplied it in his letter on the subject in your issue of Dec. 20th. He says: "The diagnosis of disease made by a veterinary surgeon as an expert on the diseases of quadrupeds should be accepted by the surgeon as the basis on which to arrive at a conclusion, but nothing more." This is exactly the system of meat inspection carried out in this city. Dr. H. Armstrong is the meat inspector, and he calls in the veterinary surgeon to tell him what the animal died from, or what disease it was suffering from when slaughtered. I have often been consulted by Dr. H. Armstrong, and have examined many carcases for him, and I have no doubt that he will admit that he has gained a great deal of his knowledge respecting meat inspection from members of the veterinary profession; and yet, strange to say, although he depends largely upon veterinary surgeons for information, he denies their ability to act as meat inspectors. Surely, the man who has made the diseases of animals a special study, who is familiar with their cause, nature, symptoms, and post-mortem appearances, must be a better safeguard to the public against the use of diseased meat and the destruction of wholesome food than the surgeon who, without the aid of a veterinary surgeon, cannot even say from what disease the animal had suffered from during life.

I am, Sir, yours truly,

Newcastle-upon-Tyne, Dec. 23rd, 1884. CLEMENT STEPHENSON.

RUSSIAN HOSPITALS.

AT a recent meeting of the St. Petersburg Health Committee, Professor Borking, speaking of the large death-rate in the hospitals of that city said that he had come to the conclusion that the patients died mostly from weakness; for with their daily allowance of thirteen or fourteen copecks, they cannot even buy a pound of beef for broth. In addition to this, the nurses, who are very badly paid, are reported to steal the food of the patients whenever they can. Surprise is also sometimes expressed in St. Petersburg society at the rapid growth of wealth among hospital authorities.

F.S.A.—Our correspondent admits that a dual service as existing of old is an impossibility, and the division desired by him into a military and civil branch we hold to be also an impossibility. One reason for keeping the civil appointments for the I.M.O. was to have a reserve available if and when required for military service, such as the Afghan Campaign, &c. But for this, Government would very likely appoint native civilians at much lower rates of pay. The possession of a reserve body of M.O. for military service when required is the justification for keeping up high-paid civil appointments.

Prof. G. Rummo.—We cannot extend our exchange list.

UMBILICAL TUMOUR.

To the Editor of THE LANCET.

SIR,—Mr. Wyatt Pratt's case published in your last issue is worthy of record. But may I be allowed to suggest that a deviation from the old stereotyped rule of ligaturing the cord three or four inches from the umbilicus might in this case have been advantageously practised, and the ligature in the first instance placed round the pedicle of the umbilical tumour, thus saving risk of delay and suffering to the little patient. I am, Sir, yours truly,

Portland, Dec. 29th, 1884. VACY ASH, M.B.

TREATMENT OF CHARBON.

A Neapolitan Surgeon desires to obtain the opinion of English surgeons on the value in the treatment of charbon (either in men or animals) of diluted carbolic acid or iodine used subcutaneously.

Assistant had better consult a medical agent.

Mr. Chas. Kirk.—There is no practical distinction.

WANTED MORE STREET ORDERLIES.

To the Editor of THE LANCET.

SIR,—When so much is done for the public health, it is to be regretted that there are not more boys employed to sweep up the horse droppings. I notice in many districts that there are no boys, or not enough, so that much of the refuse is left to be trodden about, and contaminate the atmosphere. I am, Sir, your obedient servant,

Blackheath, Dec. 22nd, 1884. C. H. BIERSTED.

Non de Plume had better communicate with the Dean of the Faculty, Dr. Béclard, à l'Ecole de Médecine, Paris.

A Medical Student.—The principal rightly claims the fee.

Clinical Lectures
ON
CASES OF DIFFICULT DIAGNOSIS.

By SAMUEL FENWICK, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE II.

STRICTURE OF THE ILEO-CÆCAL VALVE.

(*Concluded from page 3.*)

You will remember that we found that the male sex is much more liable to all forms of acute disease of the cæcum than the female, whether it be typhlitis, ulceration of the appendix vermiformis, or ileo-cæcal intussusception; but you will now see that the contrary is the case as regards contraction of the ileo-cæcal valve; for out of twenty cases in which the sex is recorded, fourteen were females. If we analyse them according to the morbid conditions coexisting with the stricture, the same circumstance is apparent; thus both of the cases supposed to have arisen from invagination were females, six out of eight cases of cancer, and four in which contraction alone is recorded were all of the same sex. The only exception is in the group in which the valve is said to have been indurated, and which I have suggested may have arisen from syphilis, for in these four were males and only one was a female. Of course, these figures are too few to justify us in drawing any general conclusions; but, like the corresponding case of the greater tendency in the female to contraction of the cardiac valves, they seem to point either to a greater liability of the female to contraction after inflammation, or to some difference in the conditions under which she is placed. It will be interesting to examine the time of life at which the complaint is most apt to occur. The age is mentioned in only sixteen of the twenty-six cases I have been able to collect, and of these ten were between twenty and forty years of age. If, however, we exclude those in which cancer is stated to have been present, we find that eight out of ten were between twenty and forty, and as the other two are stated to have exhibited induration, it is not improbable that these may have been connected with malignant disease. We should bear in mind this fact in the diagnosis of any particular case, for most of the diseases with which we are apt to confound simple stricture of the ileo-cæcal valve are especially apt to occur at an early or at a late period of life.

It will be remarked that the disease commenced differently in the three cases I have narrated. In the first the patient was attacked suddenly with diarrhœa and pain in the abdomen, and after an illness of eight days these symptoms subsided, but were gradually followed by those of intestinal obstruction; in the second the first indication of illness consisted in a sensation of movement and of pain in the abdomen, attended with swelling; whilst in the third griping pains first attracted the patient's attention. In twelve out of sixteen of the cases I have collected and whose histories are recorded, the first symptom was pain in the abdomen, usually of a colicky character; in five vomiting was also present, and in three severe constipation obliged the patient first to seek for medical advice.

In the cases in our wards attacks of colicky pain formed the most noticeable symptom through the whole course of the illness; at first coming on only occasionally, but increasing in frequency and severity as the disease progressed. Of sixteen recorded cases this was the prominent symptom in eleven; in most of them its spasmodic character was specially noticed, and in some a rumbling of the intestines at the end of each paroxysm of pain is also stated to have been present. Abdominal distension was noticed in twelve, and vomiting was a well-marked symptom also in twelve cases. In one case vomiting was the chief symptom, and lasted for many years, the patient being looked upon as hysterical, but after death the only morbid condition that could be discovered was stricture of the ileo-cæcal valve. In five instances the bowels continued to act regularly for some time after severe pain had been complained of, but generally constipation came on at an early period, and was removed by purgatives or enemata, but returned, and eventually the symptoms of complete intestinal obstruction were developed. It should, however, be borne in mind that even after the bowels—as in Case 3—cease to act, occasional small stools may be passed; and why I wish to press this especially upon your notice is because this circumstance has often led to the delusive hope that the obstruction was about to be overcome, when, in reality, the ill effects of intestinal distension were increasing day by day. A certain amount of tenderness on pressure has been observed in some instances, but general tenderness was not present, excepting when peritonitis had been excited by perforation of the intestine. Of course, the whole system sympathises with the state of the intestinal canal; the tongue becomes furred or dry, the appetite fails, thirst is a prominent symptom, in some instances there is a rise of temperature, and the pulse becomes quick, out of proportion to the other symptoms, having varied in five cases from 100° to 120°.

In two of the cases I have collected a tumour was discovered in the right side of the abdomen, but in each it was found after death to have been connected with a disease of the cæcum which coexisted with the stricture of the valve, and in none of our own cases was there any appearance of a tumour. In the three cases I have narrated the movements of the small intestines were distinctly visible through the abdominal walls, and in seven out of sixteen cases I have collected particular mention is made of this circumstance, and in only one it is stated not to have been present. As this is a most important physical sign in all cases of obstruction of the intestines, it will be necessary for us to devote some attention to its consideration. You must be careful not to confound it with the slight movements of the intestines which you will occasionally observe in females who have had repeated pregnancies, and in some children with very thin abdominal parietes. In these the colon often projects across the umbilical region, and as you watch you will see its shape and position gradually, but slowly, change. But there is no active contraction, no writhing motion, as though the canal were thrown into spasmodic efforts to force along its contents, as in cases where there is a constriction in the canal. Again, the motions of the stomach are occasionally capable of being seen, as you were able to observe in two cases that have been lately in our wards, but in these the movements are always slow, the elevations are much broader than where the intestines are affected, and you have the symptoms and physical signs of stricture of the pylorus to guide your diagnosis. Then you will naturally ask why the movements of the intestinal canal should be so increased as to be visible. This circumstance had long attracted the attention of practitioners, as occasionally occurring in intestinal obstruction; but Dr. Hilton Fagge first insisted upon it as a sign of hypertrophy of the muscular coat, and there is no doubt that his opinion is correct, as in every case that has fallen under my notice wherever the motions of the stomach or intestines have been visible the muscular coat has been found on post-mortem examination to be thickened. The visible movements of the intestines have, in fact, the same value in the diagnosis of an obstruction in the canal as the increased impulse of the heart has in cardiac disease. You detect, for example, a systolic murmur over the aorta, and you are in doubt whether it is merely functional or is produced by a narrowing at the aortic valves. In order to determine the point, you examine the apex of the heart to ascertain if there is an increase in its impulse and a deviation from its normal position; for if this is the case, you know the ventricle has become hypertrophied from the increased action required to drive the blood through the constricted opening. In like manner, when you see the intestinal contractions so much increased as to be visible through the walls of the abdomen, you feel certain their muscular coat has become hypertrophied from increased efforts to overcome some obstruction to the progress of their contents. In the case of the heart, you know that its impulse may be unusually apparent, because the chest walls are very thin; and so, as I have said before, the motions of the intestines, although no hypertrophy is present, may be seen through very attenuated abdominal parietes; but in either case you diagnose hypertrophy by the increased force with which the contraction takes place. Hypertrophy of the heart occurs whenever there is difficulty in the transmission of the blood through the vascular system, even though the valves may be healthy, as you see daily in cases of chronic Bright's disease; and in like manner any long-continued impediment in any part of the intestinal canal will give rise to visible movements of the intestines of the

same character as those apparent in stricture of the ileo-cæcal valve.

There is another physical sign which was observed in a case recorded by Dr. Wickham Legg, and which was found after death to have been produced by the collection of cherry stones in the ileum. It is described in the words of the reporter thus: "In the left iliac fossa and a little above the left flank a most singular phenomenon, both of sound and feel, was discovered. In regard of sound it is like dryish crackling, not unlike surgical emphysema; is by others likened to peas in a drum shaken about, by others to marbles." As, however, I have found only three cases in which there was any collection of foreign bodies above the stricture, this sign is not likely to be of much use to us in diagnosis. All the symptoms we have considered arise from the efforts of the intestines to overcome the obstruction to the onward progress of their contents, but as the constriction is often a very slow process, no functional disturbances may be produced so long as there is a tolerably free opening into the cæcum. This is the most probable explanation of a few cases that have been placed on record, in which the contraction of the ileo-cæcal valve was accidentally discovered after death, the patients having suffered no inconvenience during life, and having died of other diseases. Thus, in one case death took place from typhoid fever, in another it was caused by pneumonia, and in a third by tuberculosis.

We can only reckon the commencement of any particular case from the time at which the patient first experienced pain or other symptoms resulting from obstruction, and we find the duration of the disease varies both with the condition of the stricture and the cause producing it. When it was connected with cancer, two died within one month, one in five weeks, one in three months, another in five and another in six months. Vomiting was a prominent symptom in all, and death seemed to result solely from intestinal obstruction. When the stricture was independent of cancer, one died within one month, three between one and three months, one suffered for two years, one for seven and another for twenty-one years. The case supposed to have proceeded from intussusception lived only five months, whilst that beginning with perityphlitis lived eleven years. Putting aside those connected with cancer, the duration of any particular case seems to depend chiefly upon the narrowness of the stricture and upon the amount of relief that may have been afforded by a circuitous route established between the small and large intestines.

The diagnosis of this disease is attended with great difficulty, and you must, in any case where you may suspect it to be present, bear in mind its extreme rarity. The chief points to remember are that it occurs most commonly in the female between the ages of twenty and forty, that the prominent symptom is the frequent attacks of severe colicky pain attended with constipation and vomiting, and that active movements of the intestines are visible through the abdominal parietes. If you find such conditions, you know there is an obstruction in some part of the intestinal canal, and you have to determine its seat and the condition that has produced it. The first point is to ascertain whether the stricture is or is not in the course of the large intestine, for in the majority of cases of narrowing of the intestine the sigmoid flexure or the rectum is the part affected. If such is the case you often have a history of the passage of blood or mucus, or the fæces may have been of very small size, and in many cases you can prove the existence of the stricture by the finger or by a bougie passed up the rectum. If, on the other hand, the ascending colon or the cæcum is the seat of stricture, a tumour can be generally distinguished in the right side of the abdomen, for in this situation it is almost always the result of cancer. When a stricture is situated at the cæcum there are usually well-marked dulness and distension on the right side of the hypogastrium, whilst the opposite side is the seat of these signs in case the upper part of the rectum is involved. It is often said that when the left side of the large intestine is constricted the colon projects in the umbilical or epigastric region, whilst the umbilical and lumbar regions are comparatively flat if the stricture is in the small intestine. This, like all other general rules, although often of value, is not always to be relied upon; for we not infrequently see the colon so lengthened and displaced that it seems to fill the whole of the abdomen; whilst, on the other hand, a distended small intestine may be pushed upwards so as to occupy the epigastrium, and may consequently simulate the appearance of a distended colon. You might expect that when the colon was constricted the visible movements of the intestines would be directed to the left side, and that they would tend to the right if the stricture was in the small intestines; but it is in most cases impossible to determine in what direction the intestine is really moving, for a number of coils seem to be everywhere twisting about at the same time. What will perhaps be your best guide is that in stricture of the small intestine the motions are more energetic, the coils seem to be shorter and change their position more constantly, and the gurgling sound produced is moister, and gives you more the impression of the motion of fluid and gas intermixed than when the colon is the seat of the obstruction.

You may confound chronic cases of ileo-cæcal intussusception with the disease we are considering, for in both frequent attacks of colic are a prominent symptom. But the former is most common in children and in males, whilst constriction of the ileo-cæcal valve presents itself generally in females of middle age; in intussusception you have occasional discharges of blood or mucus, and there is almost always a tumour to be felt, which is apt to change its form, consistence, and position from day to day.

Constriction of the small intestine, whether produced by adhesion to some of the neighbouring organs or by contraction of the mesentery, may give rise both to the symptoms and physical signs of stricture at the ileo-cæcal valve; indeed, this was diagnosed in Case 2 as the probable cause of the patient's sufferings, as pelvic tumour was discovered, and there was a history of extra-uterine fœtation. You will only be able to arrive at a correct conclusion by making a careful examination of the pelvic organs in order to ascertain if there is any disease of the bladder, uterus, or ovaries likely to have given rise to local peritonitis. If, for example, carcinoma of any of these organs were discovered, constriction of the small intestines from adhesion would be a more probable diagnosis than simple stricture of the valve. You might imagine from the manner in which the intestines are often found to be matted together in tubercular peritonitis that intestinal obstruction would often occur from this cause. This may sometimes take place, but as ulceration of the mucous membrane is also usually present, diarrhœa, and not constipation, is generally the prominent symptom.

Cancer of the peritoneum frequently gives rise to constriction and obstruction of the intestines. When the disease is, as is usually the case, associated with ascites and with abdominal tumours, the diagnosis is tolerably easy. But there is another and more rare case, in which the cancer is scattered over the peritoneum in a miliary form, and in which attacks of colic are for some time the only prominent symptom; and here it would be a matter of great difficulty to arrive at a correct diagnosis in an early stage of the disease. You should in such instances always examine by the rectum, for often small tumours are to be felt in Douglas's pouch, when they are nowhere else to be discovered; and if in addition to the presence of a tumour you find a gradual loss of flesh and strength, the occurrence of ascites, or an implication of some other organ, you have facts that will enable you to arrive at a correct conclusion.

The first two cases occurring in our wards were treated by morphia, in order to relieve the pain from which the patients suffered, whilst the action of the bowels was assisted by enemata, but only temporary relief was afforded. There was no obstruction in either case, and the patients both died suddenly from collapse. In the third case the patient was admitted on account of obstruction of the bowels, and although some slight evacuations were obtained by enemata, he was not relieved until the small intestine was opened by operation and its contents evacuated. He died not of obstruction, but of pneumonia. It will be remarked that in none of these cases was the communication between the ileum and the cæcum completely closed; in the first there were two or three small openings, in the second a quill could be passed, and in the third the valve admitted the point of the finger. There was, therefore, nothing that was necessarily fatal, and we can only attribute the unfortunate terminations to the great and long-continued distension of the intestines and the effects of this upon the nervous and vascular systems. Now, in any future case of this kind, what treatment should be adopted in case the diagnosis was sufficiently clear to enable us to fix upon the ileo-cæcal valve as the point of stricture? We have no medicines that can prevent the gradual contraction that occurs after chronic inflammation of the ileo-

cæcal valve any more than we can stop a similar change in the mitral or aortic valves of the heart; and although, when we have reason to suspect syphilis as having originated the disease, we might employ medicines appropriate for that disease, it is unlikely that we could restore the part to its original condition by means of mercury or iodine. Clearly, then, the only plan to afford relief is what was done in the third case by Mr. Waren Tay—viz., to make an artificial opening into the small intestine near to the cæcum. The proper method of performing such an operation falls within the province of the surgeon, but I would advise you, in case you should have to undertake it, to read the account of a successful case of opening of the small intestine that was under the care of my colleague, Mr. Macarthy, which was published in the Medico-Chirurgical Transactions for 1872. It is true the patient eventually died, but the operation was successful in affording relief, and the wound had healed some time before death took place. There seems indeed no reason why an artificial opening should not be made into the small intestine with a fair prospect of success, if the same precautions be taken as in other operations on the abdominal cavity. But the chief point is, not to delay it until the portion of the canal above the stricture has become paralysed, or the heart has been so much depressed, through the sympathetic, that collapse is imminent. I have mainly brought these cases before you to impress upon your minds that all strictures of the intestines are not cancerous, and therefore not necessarily fatal, that the hypertrophy of their muscular walls affords a most valuable sign that constriction has been for some time in existence, and not likely, therefore, to yield to medical treatment, and that the interference of the surgeon may not only afford temporary relief, but restore the patient to a state of comparative health.

Lecture
ON
AFFECTIONS OF THE THROAT AND NASAL PASSAGES ASSOCIATED WITH DISEASE OF THE MIDDLE EAR.

BY W. B. DALBY, F.R.C.S., M.B. CANTAB.,
AURAL SURGEON TO ST. GEORGE'S HOSPITAL.

LECTURE III.

GENTLEMEN,—Inasmuch as a very large number of the conditions which affect the middle ear and are included under the general term catarrh are the direct consequence of a morbid state of the throat and nose, or, to speak more accurately, of the pharynx and naso-pharynx, it is important for the clear understanding of diseases of the ear to properly estimate and recognise these conditions. Moreover, diseases in this situation not only precede ear affections, but are very frequently coexistent with them during their entire course, sometimes extending over a period of many years. Before you attempt to acquaint yourselves with the chronic morbid states of the throat and nose, consider for a moment what are the circumstances under which the acute forms most usually come under the notice of medical men. Putting on one side for the moment syphilis, there remains inflammation as it appears associated with all the fevers, including diphtheria and whooping-cough. Thus you will find that the seeds of most diseases of the throat and nose, except polypus, are generally laid in childhood, when the subjects of these troubles have suffered in early life from the exanthematous fevers to which they are so readily exposed. In scarlet fever, measles, chicken-pox, small-pox, diphtheria, and the like, that considerable area of mucous membrane which covers the pharynx and nasal passages is throughout affected, so that, as might be expected, long after these maladies have been recovered from, a greater or lesser part of this area is found to have undergone change. There is little doubt that, if during the acute stages of these fevers more attention were paid to the local state of the nose, so many cases of troublesome chronic affections would not be seen. Very naturally at such times the more serious condition of the patient absorbs and demands all the care which can be given; and even during convalescence the state of the nostrils, although there is often a muco-purulent discharge from them, is not so strictly watched and treated as it might be. Hence, therefore, the great prevalence of chronic catarrh of the pharynx and nares, which, beginning at the time of the acute febrile state, remains for years, or even during the remainder of a life. Hence also the various conditions which lead to what is popularly called throat deafness, a safe and useful term to apply to a disorder if the cause and precise nature of it are imperfectly understood.

In examining a case of chronic catarrh of the middle ear, either with or without obstruction of the Eustachian tubes, you will constantly see, on looking at the throat, thick tenacious mucus adhering to the upper part of the pharynx, and with this, what is termed a granular pharynx—that is, the back of the pharynx is seen to be studded with separate granular bodies, which in severe forms of this state are so numerous that two or three run into one. This appearance is due, according to Politzer and others, to swelling of the follicles in the submucous connective tissue. The morbid state often involves the posterior nares, the upper and back wall of the pharynx, and, by extension to the opening of the Eustachian tubes, causes obtruction to the passage of air to the tympanum. In this region—viz., in the upper and back wall of the pharynx—is found the adenoid tissue which was first described by His, and excessive development of this tissue takes the form of what are spoken of as adenoid vegetations or growths. To Meyer of Copenhagen, in 1868, we are indebted for the first complete notice of this disease, which it is now generally admitted is the very frequent cause of imperfect nasal breathing, as well as obstruction of the Eustachian tubes. But, even previouly to this, isolated cases had been observed by Voltolini and Lowenberg. In regard to this matter I shall have something to say presently. Granular pharynx must not be confused with a condition which is found in persons who have been subjected to unhealthy and debilitating conditions, such as long hours of confinement in an unhealthy atmosphere, engaged in assiduous employment, and living under generally depressing influences; I mean an appearance of yellowish spots on the tonsils and pharynx. From these spots, if they are pressed, a sort of cheesy secretion may be forced out. In this state it is enough to say that a complete change which embraces plenty of exercise in fresh good air, either at sea or in the country, will do more in a short time than any sort of medicine or local treatment that can be prescribed. When the middle ear becomes involved in this condition of throat the catarrh is acute and the tympanic membrane is generally ruptured. Some of the most pronounced cases of true granular pharynx which have been associated with obstruction of the Eustachian tubes have occurred in my practice to those who pursue their calling in all atmospheres out of doors—dusty, cold, and damp; to auctioneers and betting men, the latter shouting for many hours daily, and relieving the intervals by the free use of alcoholic drinks.

It need be no matter of wonder that some alteration in tissue should follow such undue strains and undue exposure of a mucous surface; a very reasonable penalty for exceeding the intentions of nature. In regard to the treatment of this condition, attention to the general principles of health, including the giving up of stimulants, should precede everything. This having been effected, great benefit will follow the daily use of astringent applications. Amongst these may be reckoned the painting with a throat brush the whole of the pharynx with a saturated watery solution of perchloride of iron. This can be readily done by the patient if he stands in front of a mirror, or by an attendant. In very severe cases the granulations will require to be destroyed by caustic. As, however, the posterior nares share the general condition, the patient must use twice daily an alkaline solution through the nostrils with a small nasal syringe. As I have often said before, this is to be preferred to the nasal douche, for there is no danger, as there is with the douche, of the fluid from the syringe rushing into the tympana, and exciting inflammation. As to the kind of solution, I have not as yet found anything better than the mixture of soda, borax, and chlorate of potash and sugar, which I introduced into our hospital pharmacopœia in 1873. By this treatment the mucus is expelled through the nostrils, and the patients are relieved from the unplea-

sant efforts to clear the throat, and the nasal breathing is re-established. Until this is done it is quite hopeless to expect that any local application can be of permanent service to the throat, as the external air, unless it is purified and warmed by passing through the nose, is one of the principal agents in keeping up this disorder. Adenoid growths in the naso-pharynx require a few words.

The paper on this matter by Meyer, already referred to, caused these growths to be very generally sought for whenever there was obstruction of nasal breathing associated with obstruction of the Eustachian tubes. Since that time the literature on the subject has been profuse, and the methods recommended of dealing with the growths have been as various as their somewhat hidden position might lead one to anticipate; but nothing material has been added to our knowledge of the subject beyond what may be found in Dr. Meyer's paper in the fifty-third volume of the Medico-Chirurgical Transactions. This contains a most graphic and exhaustive account of the disease, and it is not too much to say that its accuracy has been completely corroborated by all who have paid attention to this matter. The aspect of a child, or young person, who is deaf from obstruction of the Eustachian tubes, and unable to breathe through the nostrils, is very characteristic; the open mouth, the odd thick voice, the stupid look, and the fact of the patient's snoring when asleep, bespeak the condition; when this aspect is present, and when the tonsils are not found so very much enlarged, adenoid growths may be suspected, and should be sought for. It should, however, be observed that the two causes very often are found to exist together, so that it is quite possible to remove the tonsils and find the nasal obstruction still present. The search for these growths may be conducted in two ways: either by rhinoscopy or by examination with the finger.

Of the value of the first method and of its difficulties you may by attending the out-patients' department satisfy yourselves more completely and more satisfactorily than by anything I might say on the subject. It is sufficient here to observe that in a large number of patients it is not only very difficult, but practically impossible, to obtain a reflection of the posterior nares. This applies especially to young children and to grown up people in whom the pharynx is shallow. With these latter subjects there is not sufficient space between the soft palate and back wall of the pharynx to place the small laryngoscopic mirror without touching the pharynx and exciting retching. Under any circumstances it requires a good deal of practice to obtain a view. With a deep hollowed pharynx, in the manner in which I have demonstrated in previous lectures, these growths may be partially brought into view. I may repeat that the tongue should be depressed with the forefinger of the left hand or a tongue depressor. The small laryngoscopic mirror should be warmed and placed as far back on the pharynx as possible without touching it, the face of the mirror being turned from the uvula, directed a little upwards and outwards; by moving it in various directions from moment to moment a reflection of portions of the posterior nares may be obtained; the light from the forehead mirror being throughout the examination directed on to the small mirror. But a far more easy method of finding the growths, and one that is open to those who have not acquired facility in examining the posterior nares with reflected light, is the examination by touch. If the patient is seated in a chair the forefinger of the right hand, protected by a guard, may easily be introduced behind the soft palate in an upward direction; the left hand should be placed on the occiput, to support the patient's head. Adenoid growths may be readily recognised in this very simple manner by the fact that the pharynx is partially occupied by them, and by the sensation which they convey to the finger. It is as if the finger touched tissue like an enlarged tonsil. They also bleed when touched. There is one other symptom of the presence of adenoid vegetations in the vault of the pharynx, and it is one which is most distinctive of this condition. If fluid be syringed into the nostril in the inferior meatus, it will either pass into the throat or come out by the other nostril. As it is frequently necessary to order solutions to be used in this way, the difficulty experienced in using these solutions effectively will often direct attention to the presence of the adenoid growths. Indeed, where this difficulty is encountered the presence of these vegetations may be considered almost certain. It is still more so if the pinched appearance of the nose, which Dr. Meyer speaks of, is present. Whilst making an examination, if the growths are small, they may be scraped off the upper wall of the pharynx by the finger-nail and spat out, and this is all that is often necessary; indeed, it has been said by some that they never fail to completely remove them in this way. For my own part I cannot understand this, for they are often in such quantity and size as to fill the vault of the pharynx. In such instances it is necessary to make use of forceps, invented by Lowenberg, and now very generally employed for this purpose. Besides, the forefinger is often much interfered with in a shallow pharynx, and in young children, by the soft palate, which feels like a string.

Lowenberg's forceps are very easily introduced behind the soft palate, and most patients will submit to their use without an anæsthetic. Inasmuch, however, as they require to be used many times, it has been thought by some desirable to take all away that may be desirable on one occasion, and ether must then be given. It will then be necessary to use sponges fixed on to forceps or at the end of a stick, to prevent the blood trickling into the larynx; for there is always free bleeding, both in the pharynx and through the nose. When the subject of these growths is not a very small child, and the forefinger can be placed behind the soft palate, I have obtained good results by using a small scoop fixed on the end of the forefinger, and projecting only just beyond the nail—in short, a sort of artificial steel nail. With this instrument the pharynx can be rapidly and completely cleared of the adenoid growths, if they are not very large or in great masses. Any risk that might be incurred if the instrument dropped into the pharynx is obviated by having a long piece of string attached to it. There is, however, no danger of this if the scoop be made for the person who is to use it, as it is fixed tightly on to the finger like a thimble. Since the introduction of cocaine I have several times removed large pieces of adenoid tissue from the vault of the pharynx without any discomfort in introducing the forceps after a 20 per cent. solution of cocaine has been freely applied to the back of the pharynx. I must say I think it much better not to attempt to at once clear the pharynx (as it has been termed) under an anæsthetic, nor from what I have seen does it commend itself as a successful proceeding or devoid of unpleasant consequences. As general attention to adenoid growths is more or less of recent date, probably their treatment, as well as the literature of the subject, may be expected to undergo some modification. Not only very great, but almost immediate, relief to nasal obstruction follows the removal of these growths, as well as improvement in hearing. It is advisable to continue the use of alkaline solutions through the nostrils for a time, and occasionally to apply astringents, or even nitrate of silver, to the surface from which the growths have been taken away. It is satisfactory to notice that when once removed they do not return.

Closely associated with this condition is enlargement of the tonsils. General rules may be laid down in regard to them. First, they often obstruct free breathing through the nostrils. Second, very frequently they not only do this, but also keep up the unhealthy condition of the pharynx, and so become an indirect cause of obstruction of the Eustachian tubes; not a direct cause, for from their position they can never, however large, form a mechanical obstruction of these tubes. In either or both cases they should be removed. The enlargement is a true hypertrophy both of the body and follicles of the tonsil. There is a prevalent and popular idea that the tonsils should not be removed. This is due to the fact that in some instances, if the enlargement is not very great, they become smaller about the age of puberty. This is obviously no valid reason against their excision; for, in the first place, they generally do not follow this course, and if they did they are capable during the interval of being a very serious trouble. Indeed, it is often impossible to treat successfully the catarrh of the middle ear which accompanies them. If they are cut through the body of the gland, taking away about three-quarters of them, it is enough, for the rest contracts after the healing process is completed. As to the best means of removing tonsils, you will not find that those whose practice renders it necessary to constantly remove tonsils use a bistoury and forceps. They employ a tonsillotome (No. I.) or a guillotine (No. II.). After many years of constant practice in this matter I have no hesitation in strongly recommending the guillotine, which has been improved by Mr. Ewens (No. III.), and for the following reasons. Although No. I. is more simple in construction in unpractised hands the tonsil is liable to drop backwards

into the pharynx. It must then be spat out or coughed out. With No. II. the patient is apt to close the teeth on the instrument whilst it is being used, and so obstruct a view of the extent of tonsil being excised. With No. III. the bar prevents the mouth being shut, and thus a complete view is obtained of what is being done, the precise extent of what is to be removed can be judged, and the tonsil being transfixed by the instrument it cannot fall into

Ewens's Tonsil Guillotine.

the pharynx. These considerations are of great value in nervous persons, or especially with children, and outweigh any extra trouble there may be in cleaning and refixing the separate parts of the instrument.

So far as I can learn, whenever the internal carotid has been wounded in removing the tonsil, it has been done with a bistoury. With the guillotine there is generally very little bleeding, and if there is, it is not of a serious nature, and can readily be arrested if necessary by the local application of a saturated solution of perchloride of iron. I have only on two occasions known bleeding to be at all troublesome. Once some blood was swallowed, and the consequent act of vomiting constricted the vessels and stopped the bleeding; another time the iron solution stopped it. If it is necessary to excise both tonsils, two guillotines should be at hand, and the second tonsil ought to be removed instantly after the first, in order that the bleeding from the first wound may not obscure the complete view of the other tonsil.

Although in most cases of catarrh of the middle ear, where they have arisen from a diseased condition of the mucous membrane of the pharynx and nares, there is an increased flow of mucus in the nasal cavities or pharynx, there is also a condition that is termed a dry catarrh of the lining membrane of the nose. In this, notwithstanding a certain stuffiness at the back of the nose and a difficulty of clearing their passages from mucus, the anterior nares are irritable and dry, and covered with little scabs, or dry yellow flakes. Now, this morbid state is almost peculiar to children and young people. If it has existed for some years, it is often impossible to point to a cause, but I have so often seen it at periods of a few months after measles or scarlet fever, and many times after whooping-cough, that I believe it more generally starts from one of these child's complaints than from any other immediate cause. Indeed, you know that catarrh of the middle ear often dates from whooping-cough, and some years ago I so often saw this ear catarrh a few months after whooping-cough in deaf children that I became accustomed to ask whether the child had recently had whooping-cough, or if not this, measles or scarlet fever. What seem at first apparently trifling ailments so frequently succeed these diseases that they are not noticed for a long time afterwards, and their origin is unsuspected. But this is not a trifling ailment, for it is the beginning of ozæna, and when ozæna is once fairly established it is probably never cured. It may be kept in check by daily attention extending over many years, but it is not eradicated. It becomes, therefore, most necessary to recognise this dry catarrh as soon as it shows itself, for in its early stages it can be put an end to. The first consideration is to cleanse thoroughly the nares with warm alkaline washes, used with the nasal syringe. The patient's head must be bent forward, and the fluid which is passed up one nostril must pour out of the other. Until this is done the little patients cannot clear their nostrils by using a handkerchief. The nurse must be carefully instructed how to syringe the nose thoroughly. After this, when the nostrils are completely cleansed with the handkerchief, a very weak ointment, composed of yellow oxide of mercury and vaseline, should be applied inside the nostrils with a small camel-hair pencil. Under this local treatment I have found many cases of dry catarrh, in the early stage, before it had passed into ozæna, get well.

In the treatment of diseases of the middle ear it is necessary to be familiar with the fact that in a very large number of the community the septum of the nose is not placed in the middle of the organ, and that the interior turbinated bone of one side is larger than on the other. If it is ever becomes important to use the Eustachian catheter, a certain proportion of cases will be met with in which it is impossible for these reasons to do so. With others a small catheter may be passed when an ordinary-sized one cannot. It is also of some interest to notice that the narrowed meatus is oftener the left than the right, and when one ear only is affected in such persons it is generally the one which corresponds to the narrowed meatus. You are aware that other means besides the catheter are available for the treatment of disease of the middle ear, so that when these deviations of the septum exist, or when the meatus is lessened by the undue size of the turbinated bones, it will, I believe, be well for the patient to submit to the slight inconvenience, rather than to incur the penalties which may follow any energy and enterprise of a surgical kind that might be thought likely to remove it.

ABSTRACT OF

Lettsomian Lectures

ON

DISORDERS OF DIGESTION,

THEIR CONSEQUENCES AND TREATMENT.

Delivered at the Medical Society of London on Monday, January 5th, 1885,

BY T. LAUDER BRUNTON, M.D., F.R.C.P.,
ASSISTANT-PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE I.

THE subject is one of great practical interest and of the widest extent. In his work on "Digestion and Secretion," forming Part III. of Sanderson's "Handbook for the Physiological Laboratory," 1873 (London: Churchill), he had treated of the physiological processes of digestion, and should therefore pass over this section with a few general remarks. Man has been defined as a cooking animal. This definition may not be absolutely correct, and there may be some of the lowest races which are unacquainted with the methods of cooking. In contrast with this habit of man is the fact that animals eat their food raw. Man began to cook at a very early stage of his history. Long, long before the historic epoch, when man's only implements consisted of broken flints, he cooked his food by roasting, and the charred remains of bones have been found in caves along with fragments of the skeletons of the cave bear, woolly rhinoceros, and other extinct animals. Roasting was no doubt the first method of cooking; boiling was a more complex process. Water was probably first heated by putting red-hot stones into it. When pottery was made, the simpler plan of boiling the water by putting the earthern pot upon the fire would be adopted. Early man must have noted the same differences in the various pots of earthenware as we do now. Wedgwood earthenware is more resistant than almost any stone. Other pots of thin and fragile china must be handled with the greatest care. There is no difference between their wholeness or "wholth," or, as we now write it, health. Yet the wholeness or health of one vessel is strong, and the wholeness or health of the other is weak. The one will stand anything, the other must be treated with great care. Our early forefathers, when framing language, had evidently been struck by an analogy between the condition of implements they used in cookery, hunting, or warfare, those implements by which they maintained the life of their bodies, and these bodies themselves, for they applied the word health to signify soundness in both. By strong health we mean a soundness of body which, like that of Wedgwood mortar, will enable a person possessing it to go through all sorts of work, be subjected to all sorts of usage, and yet remain sound or healthy. By weak health we mean a condition of body wherein all the functions go on perfectly so long as external conditions are favourable. A strong piece of ware may get cracked by rough usage, but even then it may continue to exist, though it becomes weak. Similar conditions may be found in man. An originally strong health in a person may be weakened by various circumstances. Health

in man, as in animals, depends on the proper performance of all the functions. These functions are chiefly three:—(1) Tissue change; (2) removal of waste; (3) supply of new material. The activity of man, like that of the fire, is maintained by combustion; and just as the fire may not burn brightly owing to improper disposition of the fuel or imperfect supply of air, or as it may be extinguished from want of fresh fuel, or choked by its own ashes, so man's activity may be lessened by imperfect tissue change, and may be put to an end by an insufficient supply of new material and imperfect removal of waste products. The old proverb, "There is many a slip 'twixt the cup and the lip," shows how clearly our forefathers recognised that neither food nor drink was available for the wants of the body until they had actually been taken. Our knowledge carries us a step further than theirs; but we are apt to forget that both food and drink are useless for the wants of the organism so long as they are simply in the intestinal canal. The body may be roughly compared to a cylindrical box, through the centre of which runs a tube open at both ends, but not communicating with the cavity of the box. Anything in this tube is outside the box, just as anything in the intestines is outside the organism. The tube representing the intestinal canal may be of a different material from the outer wall of the box—e.g., more pervious. Food may be evacuated almost entirely unchanged. There is one great difference between the skin and the intestines in that the nerves of the intestinal tract are more sensitive, so that a foreign body may have exercised a greater action on the body reflexly through the nerves than it would have done in passing over the skin. The intestinal surface, again, has greater absorbent power. Solids in a fine state of division, and especially when mixed with fat, may be absorbed by the skin, as in mercurial inunctions; the mucous membranes may have the same powers, but food is usually absorbed in a state of solution. Digestion includes solution and absorption. Digestion, like the health, may be strong or weak. Some persons can take anything and at all hours, or go without all day and go through all sorts of anxiety without any disturbance; others suffer on the slightest provocation.

When digestion is imperfectly performed, we say that the patient suffers from indigestion. Indigestion may occur in those who naturally have either a weak or a strong digestion, and treatment may do much for those of weak digestion. Man, unlike a fire, is a complex machine; the different parts of his body require different materials, and the wear and tear of each must be replaced by its appropriate constituents as well as energy supplied to the whole. A mixture of foods is best adapted to supply the energy and repair the waste. Like the steam engine, we require oils and carbohydrates and also proteids, which go to repair the wear and tear of the tissues. According to Ranke about 100 grammes of proteids and a similar quantity of fats are required daily by a man, while about 250 grammes of carbohydrates are necessary. Black bread contains very nearly the proper proportion of nitrogenous and carbonaceous materials, and when taken along with a little oil or a few olives it may maintain a man in health and activity without the addition of almost anything else except that of a little salt, as is seen amongst the hardworking peasantry in the south of France. In this country we have generally a more varied diet, and as a typical meal we may take a beef-steak with a piece of fat attached, a piece of bread, some salt, and water. The solids must be reduced to a fine state of division. Salt is dissolved in a physical manner, but proteids and carbohydrates must be carried through a different process, for a chemical change of hydration must occur so that the large chemical molecules of the proteids and carbohydrates split asunder into smaller and simpler ones. The particles of beef-steak may be subdivided until the highest microscopic powers fail to discover the particles, though we have certain methods of showing the presence of particles, and even of judging of their size. Graham showed that some bodies will diffuse through an animal membrane and that others will not. Those that diffuse are generally crystalline. It is probable that the connexion between crystallisation and diffusion is to be regarded as accidental rather than necessary, and that the real cause why some substances diffuse and others do not is to be found in the varying size of their particles. Moritz Traube found that a membrane of tannate of gelatine would allow nitrate of barium with a molecular weight of 130 to diffuse through it, and would also allow of the passage of all compounds having a smaller molecular weight, but it stopped the passage of ferrocyanide of potassium having a molecular weight of 211·4. Membranes may thus be regarded as atomic sieves. The causation of certain forms of albuminuria may receive an explanation from such considerations as that membranes allow of the passage of molecules according to their size. It is supported not only by the experiments of Traube on artificial membranes, but by the behaviour of hæmoglobin in regard to diffusion (Moritz Traube, *Centralblatt für der Med. Wissensch.*, 1866, p. 114). Crystalline bodies are as a rule diffusible, and of much lower molecular weight than organic uncrystalline bodies. Hæmoglobin, though crystallisable, will not diffuse, but it has a very high molecular weight, and its chemical molecules are probably very large. Between the large molecules of myosin and starch of the beef-steak and bread, and the small ones of peptone and maltose into which they are transformed by digestion, there are a number of intermediate products. In these products the molecules are probably of varying size and diffuse with varying degrees of rapidity. Anti-albumose and hemi-albumose, anti-peptone and hemi-peptone, are some of these intermediate bodies. Fats may be absorbed without decomposition, especially if they be finely subdivided, a process which is aided by the presence of a fatty acid and glycerine, such bodies as are formed in the process of digestion. Mastication is a very important process, and the comminution of the food is supplemented by the action of the saliva which is secreted under the twofold stimulus of the taste of the food and the movements of mastication, and the diastatic ferment begins to convert the starch first into dextrine and then into malt sugar. The actions in the mouth exert an influence upon the stomach and the brain. Richet noticed that the stomach secreted juice, in a case of gastric fistula where the œsophagus was completely occluded, when mastication was practised. The secretion of saliva and gastric juice is dependent on reflex nervous action, and will not take place properly if the nerve centres be depressed. The mere act of mastication excites reflex secretion, and at the same time increases the supply of blood to the nerve centres. Some observations of Marey proved that the current of blood in the carotid artery of a horse became three times as rapid during mastication as it was before. Even if it be denied that any part of the extra current of blood in the carotid goes to the brain, the fact would still remain that the movements of mastication and sucking increased the circulation to the brain, for this has been actually observed by François Franck in the human subject. In the act of swallowing, a mechanism is set in action which is calculated to increase the blood-supply, not only to the nerve centres, but to all the glandular structures concerned in the digestive act. Kronecker has discovered that the act of swallowing seems to remove entirely the inhibitory action of the vagus upon the heart for the time being, so that the pulse becomes exceedingly rapid. Sipping half a wineglassful of water raises the pulse from 76 to considerably over 100; so that, in fact, a glass of cold water slowly sipped will stimulate the heart as much as or more than a glass of brandy. The amount of free acidity in the stomach is very slight, because the hydrochloric acid combines for the time being with pepsin and proteids, forming a compound which does not give an acid reaction. In the stomach, it is uncertain whether starch passes into sugar, but it does pass into dextrine, a fact of importance.

Albuminoids are first changed into syntonin, and then probably into pro-peptone, hemi-albumose, or para-peptone, prior to the final stage of peptones being reached. Peptones may be formed artificially, and are sometimes of great service as nutrients in disease. The cause of the bitterness of the products of artificial digestion is not yet fully known, but many organic alkaloids are very bitter. The organic alkaloids are related to albumen, inasmuch as they belong to the aromatic series of organic compounds; and several alkaloids have been obtained from decomposing albumen, and the name of "ptomaines" has been given to them. Brieger has obtained an alkaloid from peptones formed by gastric digestion. By extracting a quantity of gastric peptones with amylic alcohol, he obtained an alkali free from peptones which had an action like that of curara.

The relaxation of the pylorus at the end of three or four hours has been ascribed to the increasing acidity of the chyme, but cases of abnormal acidity occur in which the food is retained in the stomach for an excessive length of time. A new field of inquiry is opened up by the discovery of the formation of an alkaloid during the process of digestion,

and the behaviour of the pylorus may be in some way related to the action of the alkaloid.

In the duodenum the chyme is made alkaline, and those substances which have only been converted into syntonin are precipitated. The pancreatic secretion is the most energetic and general in its action of all the digestive juices. Proteids do not swell, but crumble away under its action. The peptones of gastric and pancreatic digestion probably differ in some way. Bile favours the passage of fat through animal membranes, and its action in dissolving fats is a popular means of removing oil stains from furniture. A student at South Kensington once answered that "bile is formed in the stomach, and is used for cleaning carpets." Bile tends to prevent putrefaction. The products of pancreatic digestion form a favourable soil for the growth of bacteria. Indol is formed, and causes the stench in an artificial pancreatic digestion of meat; it is due to the presence of putrefactive bacteria. Were it not for the antiseptic action of bile, the occurrence of putrefactive changes in the pancreatic digestion would probably be the rule rather than the exception. The risk of poisoning from the absorption of organic alkaloids is run if putrefactive changes in the intestines are at all extensive. The alkalinity is maintained from the duodenum to the rectum, and is thus favourable to pancreatic digestion. When working with Professor Kühne at Amsterdam Dr. Brunton was informed that coagulated fibrine which had been previously rendered soluble, but not peptonised by pancreatic juice, could be digested by pure intestinal juice, which has no action on simple coagulated albumen. Absorption of the digested food is effected by the lymphatics and veins, and changes appear to occur in the peptones immediately after entering the bloodvessels. They appear to be taken up by the red blood discs and converted by dehydration into a larger and more complicated albuminous molecule—viz., that of globulin. The blood-corpuscles thus form, as it were, a store of albuminous material, which they convey to all parts of the body and give off where it is wanted. Part of the peptones is arrested and forms glycogen in the liver, as it has been found that the quantity of glycogen in this organ is increased by the injection of peptones into the bowels. The sugar also becomes dehydrated, and glycogen is produced from it. The liver therefore acts as a wise steward, laying by provision for the organism in the times of plenty and giving it out again in times of fasting. But this is not all. The venom of vipers is innocuous when swallowed. One reason for this is that it reaches the general circulation very slowly, so that the kidneys have time to excrete it and prevent accumulation in the blood. It is the liver which is the chief agent in retarding the absorption of poisons into the blood. The liver, or, as our forefathers called it, the "porta" or gate, acts the part of a prudent porter. Poisons may be absorbed from the duodenum and discharged into the duodenum again with the bile, again absorbed, and so go round and round in a circle from liver to intestine without getting into the general circulation or affecting the heart, lungs, &c. The liver actually destroys some organic poisons, such as nicotine. Ludwig and Schmidt Mulheim have shown that peptones, when injected into the general circulation, are poisons, producing loss of coagulability in the blood and great depression of the circulation, so that even the products of healthy digestion might prove fatal if they passed rapidly into the general circulation. The function of watching over the safety of the organism is not confined to the liver. The tongue and palate are the porters which prevent obnoxious substances from being taken into the intestinal canal. As a rule, substances pleasing to the palate are useful, and not injurious, to the organism. The nerves of taste are capable of education. Cookery has a perfect right to be ranked with music, painting, sculpture, and architecture, as one of the fine arts. Only rarely does one meet with a dinner which gives one the sense of high artistic perfection.

Dr Brunton then gave a highly amusing, graphic, and attractive sketch of a dinner partaken by him when enjoying the hospitality of a City company. In the courses of an ordinary dinner an order is adopted which is thoroughly physiological, which shows that whatever men may be in other things they are not "mostly fools" in regard to the plan of their meals. The reason why soup comes first has been admirably shown by Schiff in his experiments on digestion. He showed that the stomach of an animal, which some time before had digested a full meal, had very little power to digest albumen introduced directly into it, and a similar fact was ascertained in regard to an extract made from the stomach itself. The stomach seemed exhausted and incapable of producing pepsine. But if certain substances were introduced first into the stomach, the power to digest albumen was enormously increased. To these substances Schiff gave the name of "peptogens"; dextrine and soup made from meat were the most powerful of them. Assuming that the human resembles the animal stomach, we can understand how hard-boiled eggs or boiled meat can be digested if the meal be begun with a plate of soup and a piece of bread, the bread being partly converted into dextrine in the mouth, the extractive matters of meat contained in the soup on reaching the stomach will be absorbed, and will supply to the gastric follicles the power to secrete an abundance of pepsin. Juicy meat is easy of digestion, but meat from old and tough oxen, which have been employed for years in agricultural service, will not yield peptogenic matters so readily. Fish is very easily broken up, and is thus easy of digestion. Beef is less digestible than mutton, and mutton less than fish. The breast of a chicken is very digestible. The fibres of beef are longer and harder than those of mutton, and those of mutton than those of the breast of a fowl. The muscle fibres of fish are very short and easily separated. The readiness with which the fibres can be broken up mechanically corresponds to their digestibility. The physical conformation of the muscle fibres, and not the peculiarity of the animal from which they are derived, is shown in the fact that the leg of a fowl, with its long and hard muscle fibres, is by no means as digestible as the breast. Vegetables supply inorganic salts, and probably play a part in aiding the recomposition of peptones into albuminous material of the tissues after absorption. Bread supplies additional dextrine, and the cheese albuminoids. So far as the stomach is concerned it is not easy to see why we take bread, cheese, and dessert at the end of dinner. If we remember the effect of mastication and deglutition on the circulation and nervous system, we can at once see a good reason for the common manner of terminating a dinner. If the meal be more than ordinarily heavy, or if the person be exhausted by long fasting or severe exertion, or have a weak digestion, other aid must be invoked. Alcohol is one of the most powerful stimulants, both to secretion and the circulation. Hence the value of the preprandial sherry and bitters, of the sherry with soup, of the champagne with its effervescing carbonic acid, and of the small glass of liqueur or brandy, and the like.

Provided that moderation has been exercised, no harm will result, even from a heavy meal. Moderation is a relative term. The symptoms of gastric indigestion—loaded tongue, loss of appetite, tendency to nausea, and perhaps even vomiting—on the next day result if the food has been excessive in quantity, or injurious in quality, and more especially if alcoholic stimulants have been taken in excess. Dr. Beaumont, in the case of Alexis St. Martin, saw that there were "several red spots and patches abraded of the mucous coat, tender and irritable, when the above symptoms were present." The gastric juice, then, seems to have an alkaline reaction, and very little or no digestive power; hence undigested lumps may pass on and cause diarrhœa, or the inflammation may extend to the intestines, then dulness and languor with irritability supervene, the complexion becomes muddy, and the conjunctiva slightly yellowish, with possibly severe headache; all of these symptoms point to disturbance of the liver.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY. From the report of the Committee of Management of this institution for the year 1884, it appears that the number of in-patients received was 2491, an increase of 261 over the number in the previous year, and of out-patients 271, an increase of 35. The average number of patients daily resident in the hospital was 157·1, and the average number of days of each patient's stay was 23·1. The financial position of the hospital is satisfactory, the income having been fairly proportioned to the large outlay occasioned by the extended usefulness of the institution.

THE Queen has been pleased to give and grant unto James Andrew Sandiland Grant, M.D., her Royal licence and authority that he may accept and wear the insignia of the Third Class of the Order of the Medjidieh, which his Imperial Majesty the Sultan has been pleased to confer upon him as a promotion in that Order.—*London Gazette.*

CHARCOT'S DISEASE.[1]

BY WALTER RIVINGTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL.

IN his speech at the Clinical Society Dr. Moxon said that he "would be very thankful to any member who would explain in what possible way herpes zoster threw any light on this so-called 'Charcot's disease.'" It is not difficult to establish a fair analogy between the two affections. Charcot himself refers to a case at the Hôtel Dieu, related by M. Ball, which was accompanied by pain, febrile reaction, and zona, and observes: "This complication is well calculated to demonstrate at least the neuropathic, if not the spinal, origin of the affection." The neuralgic pains often attending herpes zoster may be compared with the lightning pains which inaugurate tabes dorsalis, and which most commonly constitute the only symptom when the arthropathy is developed. The effusion into vesicles, though more distinctly of an inflammatory character, has its counterpart in the engorgement and œdema of limbs, and the hydrarthroses of joints, which are among the earliest local indications of Charcot's disease. Even the definite course and complete disappearance which are ordinarily exhibited in zona may be imitated in "Charcot's disease." "At the end of some weeks or of some months the swelling disappears, and then all returns to the normal state" in the *benignant form* of the affection. "Sometimes, on the contrary, serious disorders remain in the joints, crackings, dislocations, answering to a wearing down of the osseous surfaces and various luxations (malignant form)." These phenomena, as Dr. Broadbent pointed out, are comparable with the destructive ulcerations of skin which may be caused by herpes zoster, and the disorganisation of an eyeball which may be the result of herpes following the course of the fifth cranial nerve.

The two main factors, both in herpes zoster and Charcot's disease, may be said to be irritation of sensory nerves and trophic lesions. The same factors are present in other affections of bones of which the pathology is obscure, and strongly point to a mediate or immediate influence exercised by the central nervous system. Mollities ossium is preceded and accompanied by general weakness, profuse perspirations, and violent and persistent pains in the bones or all over the body. In all the cases known to Mr. Durham some influence had been at work capable of producing great general depression of the nervous system. Even in rickets a preliminary or attendant disorder of the nervous system is shown by restlessness, perspirations, and great tenderness of surface. Again, in cases related by Mr. Stanley under the title of Fragilitas Ossium, cases which differ from mollities in the presence of simple thinning of the walls of the bones without softening or morbid deposit, fractures arising from very slight causes were preceded by pains in the bones, or by what was termed "rheumatism" of the limbs. Is it possible that any of these cases, although occurring in women between twenty or thirty, may have been instances either of commencing tabes not then recognised or of some kindred lesion of the nervous system not yet elucidated? The fractures related by Mr. Stanley were accompanied by very little pain at the seat of the injury. In one case several fractures occurred in succession, and no union was obtained after treatment for two years.

The likeness existing between these several affections, tabetic arthropathy and tabetic fractures, mollities ossium and fragilitas ossium, and the analogy which can be drawn between Charcot's disease and herpes zoster as regards the primary disturbance of sensibility and the trophic lesions which follow in direct succession, indicate active intervention of nervous agency, and give support to the view that tabetic arthropathy is of neuropathic origin. Opposed to this rational explanation is the rather fanciful supposition that Charcot's disease is merely arthritis deformans accidentally occurring in the course of tabes, and somewhat altered from its pattern by the intervention of the nervous disease. It is urged in support of this hypothesis that whilst in typical specimens of each affection the differences between them are very startling, if a large range of specimens is taken the one affection runs into the other. Moreover, Mr. Hulke pointed out that in one individual, whilst the elbow-joint showed a predominance of tabetic characters, the knee-joint showed a predominance of characters typical of chronic rheumatic arthritis—viz., expansions and stalactitic outgrowths. In reply to this view I would submit:—

1. That puzzling intermediate forms do not prove the identity of the typical forms thus connected, but only a certain relationship, the precise nature of which has yet to be ascertained. Nowhere in nature can either groups of living beings or pathological lesions be found which do not blend with their neighbours. The existence of intermediate forms renders it impossible to frame scientific definitions which shall fulfil logical requirements. There is always an amphioxus. Lupus is an affection which has very distinctive characters, and is usually very little likely to be mistaken for psoriasis, acne, or eczema; yet there are forms of the disease which so trench on the characters of the other affections mentioned that the terms "lupus psoriasis," "lupus acne," and "lupus eczema" have been coined to describe them. Carcinoma and sarcoma, closely as they are allied, have distinctive features, but to confound their definitions there occurs an intermediate form, alveolar sarcoma, for which Mr. Butlin is obliged to assure his readers that he is not responsible.

2. It is not permissible from the occasional resemblance and intermingling of specimens of tabetic arthropathy and arthritis deformans to argue that Charcot's joint disease does not result from some central or local nerve lesion occurring in the course of tabes, until it has been clearly shown that the belief in the neuropathic origin of arthritis deformans entertained by many is unfounded. Until this is done demonstrations of affinity rather tend to support the neuropathic origin of arthritis deformans.

3. In comparing arthritis deformans with Charcot's disease regard must chiefly be paid, as Charcot points out, to the predominant characters of the lesions. Charcot admits that "it is not rare to see nodose rheumatism, common dry arthritis, coincide with ataxia," and no one in the debate described the occasional coincidences between dry arthritis and tabetic arthropathy in terms half so forcible and unreserved as those employed by Charcot himself. "Undoubtedly," he says, in his lectures, "in cases of old standing, when the articular surfaces, worn and deprived of cartilage, have continued to move on each other, the limbs being still made use of more or less imperfectly, the signs observed are those of dry arthritis—viz., eburnation, deformation of the osseous extremities, bony burrs, stalactites, and foreign bodies." Herein, very likely, lies the explanation of Mr. Hulke's observation; the affection of the knee-joint which displayed the arthritic peculiarities being of longer standing than the affection of the elbow-joint in which wearing away of bone was the main feature. On the other hand, Charcot insists that when dry arthritis occurs in the course of tabes it exhibits its accustomed symptoms, that in tabetic arthropathy there is always a predominance of wearing away over the production of bony burrs in recent cases, and that true luxations are frequent in tabes, and exceptional or only apparent and not real in common dry arthritis. The interstitial absorption which occurs in arthritis deformans along the line of pressure is always accompanied by compensatory condensation and marginal hyperplasia, characters entirely absent in the specimens exhibited at the International Medical Congress held in London in 1881. These specimens were so typical that Sir James Paget drew M. Charcot's attention to the fact that tabetic arthropathy was a new disease, and the writer of the Museum Report, following suit, affirmed that it was a "distinct pathological entity." I think it is worth while also to point out that, whilst Dr. Moxon contends that a continuance of friction would convert a specimen of arthritis deformans in an ex-cabman into a tabetic arthropathy, Charcot explains that old specimens of tabetic arthropathy assume from friction the characters of arthritis deformans.

4. If tabes dorsalis is admitted to be capable of so altering a typical example of arthritis deformans, with its attendant eburnation, marginal hyperplasia, additamentary bones, hypertrophied synovial fringes, foreign bodies, increased density of bone, thickened capsules and ligaments, and stiffened, painful joint into a typical example of atrophied worn bones of diminished density, with no inflammatory changes other than rarefaction, with flail-like and

[1] This communication contains the substance of what I had intended to say at the Clinical Society on the last night of the debate on Charcot's disease. Owing to the lateness of the hour at the time when the President's list of speakers became exhausted, I abstained from addressing the Society, for fear of interfering with Mr. Baker's reply.

luxated joints accompanied, it may be, with spontaneous fractures, or to be capable of preventing the exhibition of the typical characters of arthritis deformans, this is tantamount to admitting in a roundabout way a causal relationship between the nervous lesion of tabes and tabetic arthropathy. Such an admission must necessarily end in an unreserved acceptance of the simpler view of the occurrence of Charcot's disease as the direct effect of tabes without the intervention of arthritis deformans.

5. Tabetic arthropathies have special clinical characteristics and accompaniments which mark them off from arthritis deformans. These are the occurrence of the joint lesions at a particular and comparatively early stage of tabes—viz., after the prodromal stage and before the onset of ataxic symptoms,—a special sequence of the joint affections, the lower limbs suffering before the upper, rapid destruction of joints without pain or fever, rapid luxations, and equally sudden and spontaneous fractures. Four examples of fractures from slight causes in association with tabetic symptoms have occurred in my practice at the London Hospital, and these I will take an early opportunity to bring before the Clinical Society. In one a lesion of the knee-joint was associated with a "spontaneous" fracture of the tibia and fibula about three inches below the affected articulation. Fractures of this kind do not occur in connexion with arthritis deformans, and though scarcely referred to in the course of the debate, supply one of the strongest arguments in favour of the tabetic nature of Charcot's disease.

Since the knowledge of tabetic arthropathy became current knowledge, I have not unquestionably, to use Charcot's language, "assisted at the development of an ataxic arthropathy" in addition to the case above referred to; but in the pretabetic times I have met with one or two cases of swollen, crackling, flail-like joints, occurring suddenly in middle-aged individuals, which were diagnosed as chronic rheumatic arthritis, but which in all probability, preceded as they were by so-called "rheumatic" pains in the limbs, were typical examples of Charcot's disease. This unavoidable confusion, occurring doubtless to bygone as well as to existing observers, still casts its shadow across the path that leads to the recognition of Charcot's disease as a genuine tabetic lesion; and it may be necessary to defer a final judgment on the questions raised in the debate until further observations have been made in this country; and until the advance of physiology and pathology has dispersed the mists which still becloud the relations of the nervous system to the bones and joints in health and in disease.

Finsbury-square, E.C.

A CASE OF
MIGRAINE, WITH PARALYSIS OF THE THIRD NERVE.

By R. SAUNDBY, M.D. Ed., M.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

WILLIAM P——, aged seven, was admitted into the Birmingham General Hospital on August 31st, 1884, complaining of sickness and pain over the right eye and in the right cheek-bone. The right eye was shut. He had been suffering from sickness for three days, accompanied by vomiting, but without localised pain. A year ago he was in the hospital with a similar illness. On referring to the case-book I find that on November 7th, 1883, he was admitted complaining of pain above the *right* ear; for four days previously he had complained of seeing double. There was some ptosis of the right eyelid. There is no mention of vomiting, and there was a "very slight discharge" from the left ear, which ceased immediately after admission, and there was some "weakness of the action of the left facial nerve, especially in the lower part." Hearing was not affected on either side. He has never had measles or scarlatina; he had whooping-cough slightly. His conduct at school has been good, but he has never been bright; in fact, he frets because they call him a dunce. His mother has never noticed any facial paralysis or any discharge from the ear, except that which occurred on his previous admission, and which she attributes to the use of an instrument to examine the ear (during which he complained of pain), and for the removal of a quantity of wax. She says she has had no miscarriages; she is a stupid woman, and has had constant neuralgia for two or three years past. The father is a sharp man. There is no history of syphilis. One child died of convulsions; three others, excluding the present patient, are alive and healthy.

Present condition (Sept. 2nd, 1884): Patient is a well-nourished, fresh-complexioned, pleasant-looking child. He makes no complaint of pain and has not vomited since admission. There are ptosis of the right eyelid and paresis of the internal rectus. He sees double, and when walking covers his right eye. There is no tenderness of the scalp. There is slight want of symmetry in the naso-oral folds, so that the mouth appears a little drawn to the right side, but the upper part of the face is quite normal. The tongue is protruded straightly. He can walk well; there is no giddiness. The thoracic and abdominal organs appear healthy; his tongue is clean, and his bowels are regular. Hearing on both sides is unaffected. There is no paralysis of the soft palate. Temperature 99°, pulse 96, respiration 26; urine 1018, acid, free from albumen. On Sept. 6th Mr. Eales examined the eyes at my request, and found no evidence of any paralysis of the oculo-motor muscles, nor any changes in the fundus of either eye.

Unfortunately, this case came under my observation quite at the end of the attack, so that my account of it is not very complete, but I think it is sufficient to justify the diagnosis of recurrent migraine with paralysis of the third nerve. Such a diagnosis may appear hazardous, and perhaps would not have been made by me had I not met with a very well-marked case of a similar kind previously. Two years ago I published in THE LANCET[1] a remarkable case of recurrent migraine, in which during the attacks there were all the phenomena of paralysis of the left third nerve: ptosis, complete paralysis of the upper, lower, and internal recti, dilatation of the pupil, and paralysis of accommodation. Owing to the recurrent nature of these attacks I was enabled to study the case fully, having had many opportunities of observing them in all their stages. A very noticeable circumstance with regard to that case was that the recovery after the paralysis was incomplete, the superior rectus remaining permanently paralysed while the other recti were enfeebled. The pupil remained slightly larger than that of the opposite eye, and there was a persistent degree of ptosis of the eyelid. As is well known, a great variety of nervous phenomena have been recorded in connexion with migraine; affections of vision, taste, smell, and hearing, aphasia, partial loss of consciousness, vertigo, cramps, transient hemiplegia, numbness and tingling of the fingers; and Horner has described a form of ptosis which he attributes to paralysis of the unstriped muscular fibres of Müller which are supplied to the orbicularis palpebrarum. Dr. Wilks mentions paralysis of the third nerve among the symptoms of migraine, but cites no case, nor can I find any recorded but my own. The rarity of the condition is shown by the absence of all mention of it in Dr. Liveing's comprehensive monograph on this form of headache, and in Galezowski's more recent paper on the ophthalmic phenomena of migraine.

Birmingham.

THE SURGERY AND PATHOLOGY OF TENESMUS OF THE RECTUM.

By J. HEADLEY NEALE, M.B., C.M., L.R.C.P. Lond.

A SHORT time ago, attention was called in a contemporary journal to the treatment of spasmodic contraction of the sphincter ani by digital dilatation, a *modus operandi* concerning which most of our standard surgical text-books afford but scanty information. Maisonneuve was probably the first to bring it into notice; and Holmes, in the last edition of his "System of Surgery," speaking of an "operation that has lately been recommended in France," condemns it as "unsurgical," at the same time admitting the evidence of its success. So far back as 1877 we find Erichsen, after recommending the trial of belladonna by

[1] Vol. ii., p. 345.

suppository, which at best could only relieve symptoms without removing the cause for this distressing complaint, writing thus: "Should these means fail, the patient must be anæsthetised, and the sphincter forcibly dilated with the surgeon's fingers." As "nothing succeeds like success," the following particulars of a case I was asked to examine with a view to operative interference may be of interest.

Mrs. F——, wife of a well-to-do farmer, aged fifty-nine, nulliparous, stout, florid, and of a sanguine and neurotic temperament; menopause came on in the forty-ninth year. About eighteen years ago a tumour, supposed to be ovarian, appeared in the right iliac region, freely movable, and about the size of a fœtal head. It subsequently disappeared, and no trace of it now remains. The family history is good. Beyond a dyspeptic tendency, the occasional occurrence of piles, and of slight attacks of bronchitis in the winter months, the patient has always enjoyed good health, until about fifteen months before the date on which I saw her; when the bowels began to act irregularly, defecation becoming both difficult and painful. The abdomen was greatly distended with flatus, which, however, was scarcely ever passed per anum. There was a continual desire to go to stool, sometimes recurring a dozen times in a day; the attempt frequently proving abortive. The motions when passed were of a "flattened tape-like character;" small doses of aperient medicine were constantly required, and the pain and difficulty in defecation increased. The patient's distress from distension, and what she termed a "growing up of the bowel," was so great that she consulted her medical adviser, who resorted to daily digital dilatation, and ordered warm water enemata to be frequently administered. This course of treatment in a measure relieved the condition; but, as the patient began to look forward to the daily manipulation with much dread, a more detailed examination under anæsthesia was recommended; and for this purpose I attended in consultation with her regular medical attendant. I first made a digital examination per vaginam, and found the os uteri normal and of the usual nulliparous character. A most unaccountable fold of mucous membrane high up in the vagina apparently divided that cavity into two compartments, and offered distinct resistance to the exploring finger. Passage of the sound showed the uterine cavity to be normal both in size and axis, thus negativing the existence of a uterine origin for the disease. The patient was then anæsthetised, and a most careful examination of the rectum both digitally and by the speculum was made, but not the slightest trace of either ulcer or fissure could be found. Around the anal orifice, however, and for some distance above were visible numerous polypoidal extrusions of old and absorbed piles.

Anæsthesia being complete, two, three, then four fingers, and afterwards the whole hand as far as the knuckles, were introduced into the bowel. There was free, but at no time alarming, hæmorrhage. Soon after returning to consciousness the patient passed a perfectly natural motion, the result of an aperient injudiciously taken the night before. A warm water enema was then administered and a quarter of a grain of morphia suppository passed into the rectum. Twenty-four hours after the operation the temperature rose to 101°, the bowel was then irrigated with a solution of hyposulphite of soda (a drachm to the ounce) and another suppository administered. The temperature speedily fell to, and afterwards remained at, the normal standard, the patient making an uninterrupted recovery.

The points of interest in this particular case were:—(*a*) the presence and subsequent disappearance of an abdominal tumour in a highly neurotic female, suggesting the query, Was it of phantom origin, or was it a myoma undergoing spontaneous involution at the climacteric period? (*b*) the absence of any fissure or ulcer, or (*c*), of any uterine mischief to account for the painful symptoms; and (*d*) the presence of the sites of old and absorbed piles. Among the pleasing results of the treatment may be noted the complete cessation of these symptoms; the patient's intense satisfaction at once more being able to pass natural motions without pain; and, lastly, her uninterrupted recovery from the operation.

As regards the pathology of spasmodic contraction of the rectum and sphincter ani, where an ulcer or fissure exists the cause is not far to seek. The peripheral end-organs of a highly sensitive and complex nervous mechanism are exposed by a raw surface to the stimulus (whether mechanical or chemical) of the intestinal contents passing over them, and an inordinate contraction of both voluntary and involuntary muscular fibres is the result; but where no such evident cause exists, and nothing is to be observed save the "reliquiæ" of old and absorbed piles, we have to resort to a hypothesis for an explanation of the condition. The following appears to me to be a feasible one. On the occurrence of a pile, with its extravasation of blood, there is considerable distension of the submucous tissue; and just as inordinate distension of subcutaneous tissue by deposition of fat is followed on the disappearance of the latter by cicatrisation and the formation of "lineæ albicantes" (a condition I have frequently observed in nulliparæ of an anæmic or chlorotic tendency), in like manner may not the absorption of the clot in a pile be followed by submucous cicatrisation, involving the aforesaid peripheral nerve-endings, and inducing a condition of hyperæsthesia, on the application of a stimulus, such as the presence of fæces in the rectum? We should thus have an explanation of the "flattened tape-like" fæces; for, with the desire to pass a motion, volition is called into play for the inhibition of the sphincter; this is modified by the inordinate reflex contractions, and the balance of power in the combat results in a narrowing of the orifice, and consequent moulding of the fæcal matter. By dilating the parts we resort to a process of nerve-stretching, releasing the peripheral nerve-endings from their constricting environments, thus rendering them less amenable to the action of a stimulus, and leaving the voluntary inhibition of the sphincter to assert its mastery.

Leicester.

OSMIC ACID IN SCIATICA.

BY JAS. MERCES, M.R.C.S., L.R.C.P. LOND.

I HAVE much pleasure in bringing favourably before the profession the fruits of my observations gained in that rich field of untold treasures in the various joint affections, including certain skin diseases and neuralgic affections, which one meets with in the Bath Mineral Water Hospital, the beneficial and curative value of its waters being apparently still unknown to a great number of our profession.

I have given osmic acid a trial in eighteen cases, which have resisted all other known methods of treatment which we occasionally resort to as an adjunct to the unaided efforts of the waters, though it is satisfactory to state that only about 25 per cent. of the cases which are admitted here, having previously tried the faculty of the towns from which they are sent, resist every known curative measure, including our baths. To the latter twenty-five per cent. I have directed the subject of my observations. The patients' ages varied from eighteen to sixty-five. In twelve cases I succeeded in giving them absolute relief for a period of three weeks, when I lost sight of them, the patients having left the hospital. The numbers of injections varied from one to four. In six I gave temporary relief. The injections were as many as twelve in one case. It is perhaps instructive to state that though I did not give them permanent relief, they obtained more comfort by its use than even hypodermic injections of morphia. I used a one per cent. solution, injecting deeply over the sciatic nerve, at a point midway between the tuber ischii and trochanter major, three to five minims of the solution. It produced no constitutional effects, but locally at the seat of the puncture the patient invariably complained of a numb feeling, which, however, was transient. In some cases the effect was marvellous, the patient being able after a short time to stand on the affected side, a feat which he had been unable to do for years.

I am unable to state or propound any theory of the action of osmic acid. Its effects are undoubtedly local, and one can hardly conceive that it could set up any appreciable amount of local inflammation by its undoubted irritant property, inasmuch as its effects are so rapid. That it is, however, a valuable and fairly successful remedy I think the test of experience will soon establish.

Bath.

THE Waterworks Committee of the Manchester Corporation are stated to be about to put the Thirlmere water scheme for the city into immediate operation.

CONCERNING THE ACTION OF CERTAIN REMEDIES IN "FUNCTIONAL" AMENORRHŒA.[1]

BY THOMAS SANCTUARY, M.D.

IT is, perhaps, a fortunate thing for the chemist, and for those medical men who make a large portion of their income by dispensing, that there still exists a widespread popular belief in the virtue of drugs. That this belief is in part a natural consequence of the uncertainty which attaches in any individual case to the cause of recovery cannot be doubted; that it rests on a basis justified by scientific discovery is not so clear, and I cannot but think that a great deal too much physic is prescribed in the present day, and too little attention paid to the general hygienic treatment of the patient. At the same time it is a well-established fact that we possess a few remedies which seem to have a special action and to be of benefit in certain diseases, and I wish in this short paper to allude to two drugs, which in this country at any rate do not seem to have met with the general appreciation they deserve in the treatment of that uncomfortable and mysterious symptom, amenorrhœa.

a short unselected list of cases which, with one exception, were uniformly successful; and to induce the profession to give these remedies a fair trial in those cases of amenorrhœa for which no obvious cause can be assigned. With apiol the name of Dr. Joret of Paris is inseparably connected, as that of Ringer is with the permanganate.

The former drug was employed in Brittany about the year 1849 as a febrifuge, but as its emmenagogue properties were discovered and more powerful antipyretics came into vogue, it gradually became the fashionable remedy for amenorrhœa. It is said to cause a painless menstrual flow, and to remove the lumbar and abdominal pains which in many women accompany the period, and to have no deleterious effect in case of pregnancy. In my limited experience I have noticed occasionally that a good deal of griping and flatulence appear to follow its administration; and this, as well as the fact that it is rather an expensive drug, will cause it probably to be less used than the potash salt. Either drug may be given just before the period is expected, or at or after the usual time for its appearance. Apiol may be prescribed in capsules or emulsion, the former preferably, I think; and I generally use the imported original capsules of Drs. Joret and Homolle, which contain from three to five minims; one of these should be taken night and morning; the permanganate, in one grain doses, in pill form (made with kaolin to prevent oxidation), three times a day. It is possible that apiol acts in a somewhat similar way to savin oil, and is

Putting aside the question of pregnancy, it is often most strange why the average healthy female who has usually menstruated at regular intervals should, for no apparent cause, miss one, two, or more periods, and then resume the even tenour of her way for the rest of her menstrual life. In many cases cold, shock, hæmorrhage, or other valid reason may be assigned, but there still remains a large number in which it is impossible to find a satisfactory cause; and it is in these unexplained cases, which, for want of a better term, I will call "functional," that the value of the two drugs apiol and permanganate of potash is demonstrated. It is with much diffidence that I venture to bring these notes before the profession, because to most of them it is more than probable that the subject may be no novelty; and, secondly, because in the list of appended cases,[2] sixteen in all, there is only one record of failure; and it might seem as if, carried away by the implicit faith in the unfailing action of these drugs, I pinned my faith to them exclusively, and attempted to prove their efficiency in every case of amenorrhœa. I beg to disclaim any such pretension, nor do I believe them to be specifics; I simply wish to place on record more trustworthy. The precise action of the permanganate is uncertain, but it does not improve the quality of the blood, nor does it cure chlorosis, if that symptom be present along with the amenorrhœa. It produces a profuse, painless flow after from four to twelve grains have been taken. From what I have seen of the two drugs I prefer the permanganate. (See Table.)

Salisbury.

[1] Read before the South Wilts District Branch of the British Medical Association, July 23rd, 1884.

[2] I have since added four other cases (making twenty in all, with two unsuccessful ones).

CANTOR LECTURES.—The second course of Cantor Lectures at the Society of Arts will be on "Climate and its Relation to Health," by Dr. G. V. Poore, and the lectures will be delivered on Monday evenings, Jan. 12th, 19th, and 26th. The first lecture of the course will be delivered on the evening of Monday next, and will deal with the chief constituents of climate, latitude, heat, light, and barometric pressure; the second lecture, on January 19th, will treat of the effects of soil, drainage, and vegetation upon climate; and the subjects of the third lecture, on January 26th, will include the chief sources of atmospheric impurities, both inorganic and organic, climatic diseases and climatic health resorts.

DR. J. F. STEVENSON, J.P., Birkenhead, has been appointed a Visiting Justice for the County Asylum, Chester.

ST. THOMAS'S HOSPITAL.

A CASE OF RESECTION OF THE LARGE INTESTINE FOR SCIRRHOUS GROWTH.

(Under the care of Mr. SYDNEY JONES.)

W. K——, aged fifty-four, married, was admitted under the care of Mr. Sydney Jones on May 15th, 1884, and died on the 26th.

The family history was good, and there was no record of tumour. She married twenty-nine years ago, and had had seven children, the youngest of whom is aged sixteen. Four died from measles or scarlet fever; the others are living and healthy. She had had no miscarriages. She has suffered from herniæ since the birth of her first child (right inguinal and femoral); for these she had worn a truss, but only for two months. Six months ago she felt pain in the right side of the abdomen; this pain was worse during and after exercise, and she knew of no cause for it. Four months ago she noticed a swelling in the part of the abdomen where she felt pain; it increased in size, but has not changed in position. The pain has been worse after a hearty meal and during exercise, but she did not think that she had lost flesh, and her appetite continued good. She had always suffered from constipation, but since Christmas the bowels had been more than ever confined, and her motions had been of a dark almost black colour recently, but she did not know that she had ever passed blood. The catamenia ceased about seven years ago; until then she was quite regular.

On admission she was a thin pale woman with an anxious expression, complaining of a swelling in the abdomen. On the right side of the abdomen about the level of the anterior superior spine was a solid tumour, about two inches and a half in diameter, of very irregular outline. It appeared to be attached to the abdominal wall, did not move with respiration, but was not fixed; it could be moved from side to side. It was tender to the touch, firm and hard, and somewhat irregular on the surface. The resonance of the abdomen generally was good, but was modified over the tumour; there was not absolute dulness. The abdominal walls were lax, and there was a hernia in both the inguinal and femoral regions on the right side, the former easily descending when the patient stood, and being easily reduced with gurgling; the latter small, descending less easily. The organs generally were healthy. Urine 1027, no albumen, contained a little mucus. The patient suffered a great deal of pain and was anxious for something to be done to relieve her.

May 23rd.—The patient having been prepared for the operation in the usual manner, and the bowel cleared by an enema, she was put under the influence of ether, and Mr. Sydney Jones performed the following operation. An incision four to five inches in length was made from above downwards over the centre of the tumour, and when the abdominal walls had been divided and bleeding points ligatured, the carbolic spray was turned on, and the remainder of the operation completed under it. The tumour was found flattened and adherent to the peritoneum, and there was slight bleeding when it was separated; it was found to be situated in the upper part of the ascending and part of the transverse colon. A warm sponge was placed over the exposed intestines whilst the diseased portion was examined. It was decided to excise the cæcum and all that part of the intestine which was involved. The mesentery and omentum were ligatured by silk ligatures piece by piece, and then divided. A clamp covered with indiarubber was put on the intestine on each side of the line of proposed separation, and the intestine was then divided by scissors, and any bleeding points twisted with forceps. A small piece of sponge was inserted into the open end of the ileum whilst the tumour was being dissected out. The tumour and involved intestine were removed from the transverse colon in a similar manner. It was decided to bring the two ends together without making an artificial anus. About fourteen fine silk sutures were passed through the whole thickness of the intestine, so that the two cut ends were united around their whole circumference; others were passed through the serous coat alone, and one was passed (near the wound) so as to attach the serous coat to the abdominal wall. After the clamps had been removed there was a little ecchymosis and congestion of the gut near the place where they had been applied. The abdominal cavity was then carefully wiped out with dry warm sponges, and three sutures were passed through the upper part of the edges of the wound and one through the lower; the middle part of the wound was left open, and a light plug of iodoform gauze was inserted into it. The wound was dressed antiseptically, a bag of sublimated wood wool being used to soak up any discharge, and this was bandaged on with carbolic gauze bandages. The pulse was good after the operation. A half-grain suppository of morphia was given before the patient was put back to bed.

24th.—She complained of pain occasionally during the night and did not sleep for more than half an hour at a time, although injections of morphia were administered at seven and eleven last evening. The urine was drawn off every eight hours. Temperature last night 98·4°; this morning 100°. She had another injection of morphia in the early morning and suffered no pain during the early part of the day. Pulse 134, bounding and easily compressible; respiration easy (25); tongue dry; has taken ice only; urine 1030, acid, a deposit of lithates, no albumen, some mucus. 2 P.M.: Temperature 101·2°, patient quiet and without pain. 8 P.M.: Temperature 104·4°; restlessness, no pain. The wound was dressed on account of the rise of temperature; the plug was found covered with quite sweet coagulum; the dressing gave no pain; the spray was used. The wound looked well and there was no abdominal distension. An injection of one-third of a grain of morphia was given, after which she slept for two hours.

25th.—The patient seemed better, no pain; pulse 124 at noon, and occasionally intermittent; temperature, 2 A.M., 103·8°, 8 A.M., 103·6°, 2 P.M., 103°, 8 P.M., 102·6°.

26th.—She slept about two hours during the night after the injection of one-third of a grain of morphia. She became weaker towards the morning, and her temperature rose to 104·4° at 2 A.M. She was worse at 8 A.M., when the temperature was 104°, and a teaspoonful of brandy was ordered to be given every hour. 11 A.M.: She was sinking; the pulse could hardly be felt, temperature 104·4°. An injection of ether and a nutrient enema were given, after which she revived a little but sank, dying quietly at 1.45 P.M.

At the post-mortem examination, made on the following day by Dr. Sharkey, the abdominal cavity contained no fluid, and there was no general peritonitis. The site of the operation was the right iliac and lumbar region, where the small intestine had evidently been united to the large after a portion of the bowel had been removed. The line of junction was very vascular, but there was no inflammation except at the point where the mesentery was attached; here dirty-looking pus had infiltrated the tissues. Water injected through the gut passed freely and easily by the seat of the operation; but on putting a little more pressure a larger, but still moderate, stream of water trickled through the wall of the gut at the junction of the mesentery with it. This slight oozing was probably the cause of the local inflammation. There was a moderate degree of atheroma of the valves on the left side of the heart; the lungs were both greatly congested and œdematous in dependent parts; the kidneys were rather small, and their capsules very slightly adherent; otherwise the organs were healthy.

Remarks.—Having little doubt as to the nature and seat of the growth, and taking into consideration the inevitable ending if no operation were performed, either from local extension and involvement of surrounding parts or possibly obstruction of the bowel from diminished calibre of the gut—the patient suffering much pain from the growth, which was increasing somewhat rapidly in size, and being anxious for relief—Mr. Sydney Jones performed the operation described above; and the general and local condition (there being no enlargement of the neighbouring glands nor visceral disease, as proved post mortem) justified the expectation of a successful result.

BOURNEMOUTH COTTAGE HOSPITAL.

A CASE OF BULLET WOUND OF THE SKULL; RECOVERY.

(Under the care of Dr. DOUGLAS.)

FOR the following notes we are indebted to Mr. T. Fred. Gardner, L.R.C.P. Lond., M.R.C.S., late resident medical officer.

Charles C——, aged twenty-eight, a labourer, was admitted at 9.30 P.M. on August 13th, 1884, with a bullet wound passing through the left eyebrow. The wound was inflicted by the accidental discharge of a smooth-bored gun within two yards of the patient's head. This accident took place at a shooting gallery on the beach, and a leaden bullet subsequently obtained from the owner of the gallery as one similar to that with which the gun had been loaded weighed three drachms, and was the size of an ordinary playing marble.

The patient, when admitted a quarter of an hour after the accident, was quite conscious, able to speak, and breathing tranquilly. He had a very feeble pulse, cold extremities, and his face was bathed in perspiration. The pupils were normal and equal. There was no paralysis, no loss of sensation, no impairment of vision. The patient complained of pain at the seat of injury, but nowhere else. The wound was situated in the left eyebrow, about half an inch outside the supra-orbital notch. It was quite circular, with clean-cut edges, which were inverted. The diameter of the wound was a little smaller than that of a sixpence, and at its upper margin two small dark lines, about one-eighth of an inch long, ran out at right angles from the border of the wound, as though some slight laceration had taken place at this part. Dark venous blood escaped from the wound, the flow increasing whenever the patient moved, and especially when he coughed. The margin of the wound was slightly blackened. A small fragment of lead corresponding to a projection on the sample bullet from defect in the mould was found lying in the wound. This and a small fragment of bone about the size of a millet seed were extracted from the wound. On passing a probe into the wound a short distance several loose pieces of bone could be felt. The probe being withdrawn, the wound just admitted the entrance of a small finger. With the finger so inserted a perfectly round perforation could be felt in the frontal bone, with sharp bony edges, and the brain was felt pulsating against the tip of the finger. The bullet could not be felt, nor could any trace of it be found between the scalp and skull. There was no other wound in the head. A piece of lint soaked in carbolic oil was applied to the wound, and the patient carefully put to bed, ice being applied in an ice-cap to the head. Milk diet was ordered, and a nurse appointed to watch the patient. During the night he was restless, and slept only at intervals. A quantity of blood oozed from the wound at every movement.

14th (second day).—No change had taken place in the patient's condition. He was still conscious; hæmorrhage had continued, movement or coughing increased the flow considerably. When the patient was quiet, the blood in the wound was seen to pulsate synchronously with the patient's breathing. The patient now complained of pain at the back of the head near the occipital protuberance. He had not passed any urine and had no desire to do so. Pulse 60; temperature 98·2°. Towards evening some effusion appeared under the left upper eyelid. Ice to the head was continued.

15th. The patient still conscious, the pain at the back of the head not so bad. He was a little restless through the night. Had passed about a pint and a half of clear urine early in the morning. Pulse 60; temperature 98·4°. Except the restlessness there has been no symptoms of cerebral inflammation, irritation, or compression.

16th. The patient feels no pain, the wound is scabbed over. The effusion and swelling of the upper eyelid have not at all subsided. His bowels not having been opened since admission, an enema was administered, and it has acted. Towards evening the patient said he felt quite well. Pulse 60; temperature 98·4°. The ice to the head continued, and beef-tea and some light pudding added to the milk diet.

17th. No change in the patient's condition during the last three days. Bowels have been unrelieved since the 14th. Temperature being still normal, the ice to the head was discontinued.

20th.—The patient more drowsy. He falls asleep over his food, but can easily be roused; he complains of no pain. The pupils are markedly unequal; this is the first time they have deviated from the normal. Pulse 45; temperature 98·4°. An ounce of compound senna draught ordered and given, but the bowels remain unrelieved.

21st.—The patient is still drowsy. Two enemata failed to open the bowels. He was a little sick. One minim of croton oil in mucilage was given and rejected. Pulse only 45.

22nd.—Bowels still unrelieved. Four grains of calomel were given in the morning and repeated in the evening. He was not quite so drowsy. Pulse 54.

23rd.—Five grains of compound powdered elaterium administered in the morning and repeated at night as the bowels did not act. Pulse 54.

24th.—The bowels acted copiously during the night. The patient is much brighter. Pupils are equal (they have been unequal since the 20th). Pulse 60.

26th.—Bowels acted naturally. The patient is cheerful. Towards evening he complained of pain and throbbing in the wound. Pulse 60.

27th.—The pain in the wound has gone. There is no tenderness, no fluctuation, nor any crepitation about the wound, which remains scabbed over. Patient feels quite well and wants to get up. The tongue is quite clean, but the bowels have not acted since the 26th.

28th.—The patient is not so well. The left upper eyelid is red and swollen, but no fluctuation can be detected. The left pupil is more contracted than the right. Morning temperature 98·4°; pulse 84. The bowels being still confined five grains of compound powdered elaterium were given. The patient had a rigor at 11 A.M. Temperature taken after the rigor, which lasted a quarter of an hour, was 100·8°; pulse 96. The patient is irritable, restless, and refuses all food. He was sick in the middle of the day. Ice was applied to the head. At 6 P.M. the temperature had fallen to 98·6°, and the pulse to 84. Bowels still confined, so the elaterium was repeated at night. The patient was sick during the night. Temperature, 11 P.M., 101·8°.

29th.—Bowels still unopened. The wound opened in the night, and a little pus escaped. The eyelid is still swollen. Morning temperature 98·8°; pulse 96. A director was passed into the wound, and a sinus passing inwards between the bone and skin was opened up with a bistoury. A small quantity of pus escaped, but no bone. A poultice was applied. The patient was very restless during the day. Very offensive-smelling pus escaped from the wound, but only in small quantities.

30th.—The patient slept well during the night, and the bowels were freely opened. Charcoal poultices were applied during the day to the wound. Morning and evening temperature normal; pulse 54.

31st.—The wound still discharging an offensive-smelling pus, but no bone comes away. The patient could raise the still swollen eyelid a little; vision is unimpaired; pupils remain markedly unequal.

Sept. 1st.—The patient is better; swelling of eyelid gone down; pupils nearly but not quite equal; temperature 98·4°; pulse 72.

2nd.—The wound is healing. A little pus, quite healthy but odourless, escapes. Pupils are equal. Temperature and pulse normal.

3rd.—The patient is a little drowsy.

4th.—The drowsiness passed off, and the patient felt quite well.

10th.—The patient was allowed to get up.

12th.—Allowed to walk into another ward.

20th.—Allowed a walk in the garden.

30th.—The wound is still open; it presents a mass of large-sized granulations covering an area the size of a sixpence. They are touched daily with nitrate of silver and dressed with cold water dressing. The patient is very excitable at times, scarcely knowing what he does. He sleeps badly.

Oct. 1st.—The patient was discharged from the hospital after seven weeks' residence.

8th.—The patient reported himself at the hospital. The wound is still open and discharging a small quantity of healthy pus. No bone has come away.

13th.—The patient has had occasional attacks of giddiness, similar to attacks he had after a sunstroke some time ago. The wound is still open.

25th.—The patient was present at a tea given to old in-

patients of the hospital. He was still excitable. The wound was still open, all attempts to heal it having failed. It was still being touched with nitrate of silver by his club doctor.

Dec. 11th.—Patient came into Bournemouth by train. He was feeling well in every respect. The wound was still open.

12th.—The following is a report from his doctor: "C——'s health during the past two months has steadily improved. The excitability and moroseness of temper, then sometimes present, have passed off, and although he suffers occasionally from sleeplessness, still this occurs much less often than before. The wound has contracted much, but as there is some tendency to accumulation of pus between the right (*sic*—? left) upper eyelid and orbit, I have not encouraged the entire closing of the wound made by the bullet. The amount of discharge is only a drop or two each day. The boy's intellect is perfectly clear in every point, and there is not the slightest trace of paralysis anywhere, nor of any symptoms of irritation of the brain."

Remarks.—There seems to be no doubt in this case that recovery has taken place while a leaden bullet, weighing three drachms, remains within the skull. The clean-cut wound, the hole in the frontal bone, and the pulsation of the brain seen in the wound leave but this one conclusion, that the bullet, travelling with considerable force, really entered the skull. The situation of the bullet is not so clear. The absence of all sign of convulsive movement seems to favour the theory that the brain escaped injury. It is probable that the bullet remains between the brain and the dura mater, and either rests on the orbital plate of the frontal bone just below the wound, or has rolled into the base of the skull. Mr. Erichsen, in his work on Surgery, quotes the case in which a bullet entered the right temple, passed across the brain, and splintered from within the bone on the left temple, but causing no external wound there. On cutting down to the splintered bone on the left temple the bullet was not found, but post mortem it was discovered lying loose in the base of the skull, where it had rolled. This may have occurred to the bullet in this case. Points of interest in this case are—1. The absence of all meningeal or cerebral inflammation, although the dura mater was shot through and irritated by numerous particles of bone. The rigor and rise of temperature noted were evidently caused by the accumulation of pus under the scab, as immediately its evacuation was accomplished the temperature fell. 2. The obstinate constipation due to complete loss of nervous power over the intestinal tract, and resisting nearly all purgatives. 3. Compression of the brain, probably by the bullet, the temperature remaining normal, so excluding any compression from inflammatory effusion.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Fracture of the First Rib.—Simple Fracture of Skull in Infants, followed by Pulsating Tumour.

THE annual general meeting of this Society was held on Tuesday last, Mr. J. Whitaker Hulke, F.R.S., President, in the chair.

Mr. CHARTERS SYMONDS read the report of the Morbid Growths Committee on Mr. Barker's case of a tumour of the upper jaw. The report drawn up by Mr. Symonds and Mr. Bowlby was lengthy, and illustrated by three good drawings, showing the variety and arrangement of the histological elements of the tumour. The conclusion was arrived at that the tumour was a specimen of spheroidal-celled carcinoma of the variety called adenoid or glandular.

Mr. ARBUTHNOT LANE described two cases of Fracture of the Right First Rib alone, and one of Fracture of the Right First Costal Cartilage alone. The first occurred in a woman, the fracture being situated one inch and a quarter outside the tubercle. There was but slight displacement; union was complete. The second was found in a man. The rib had given way just outside the scalene tubercle. As the subject was affected by rheumatoid arthritis, the ends of the bones were flattened, eburnated, and rendered very thick by marginal bony growth. They were surrounded by a loose fibrous capsule. This fracture had evidently taken place during vigorous adult life, as no articulation of any sort exists in the now completely ossified right first cartilage, while a complete and loose arthrodial joint exists in the one on the left side. The presence of the ununited fracture in the right rib obviated the necessity of the formation of the joint in the right cartilage. This case had an ununited fracture of the right acromion. Mr. Lane put forward three possible hypotheses as to the mode in which the first rib was broken. The first was force applied directly to the seat of fracture. This could only occur when the fracture was situated near the tubercle, and was a very unlikely means, as the rib was at this point covered by the scapula and much muscle. The second was that it might be broken by force applied directly to the manubrium. This was improbable, owing to the great obliquity of the first arch. The force required to break the rib in this way would be much more likely to cause fracture or dislocation of the sternum. The third, and he considered the most probable means, was force applied to the clavicle, and transmitted to the first rib. He referred to a paper in the last number of the Transactions, "One Mode of Fracture of the Sternum," where he had already shown that it is by transmission of force to the first rib by the clavicle, and by this to the first cartilage and manubrium, that fracture of this cartilage or of the sternum is produced. He now wished to prove that the first rib alone is fractured in a similar way, and that the seat of fracture of the rib depends a good deal on the direction of the force applied to the clavicle. In his first case he thought that force had been applied in a backward direction, and in his second case in a vertical direction. He remarked on the supposed extreme rarity of this fracture, and referred to a case briefly described by Mr. Lyell in "Holmes' System of Surgery." He also showed a specimen in which the right first costal cartilage alone had been fractured one eighth of an inch from its outer extremity. It had not united very firmly, though it was surrounded below and in front by much irregular callus. He considered that it had been broken by force transmitted vertically through the clavicle.—Mr. HULKE said the most important feature was the causation.—Mr. CLEMENT LUCAS said we were indebted to Mr. Lane for the paper on account of the rarity of the accident, the causation was no doubt the most interesting part of the case. It would perhaps have been better if the clavicles had been retained in position in the specimens shown by Mr. Lane. Mr. Lucas had seen but one case in which a cart-wheel had gone over the clavicle and had broken it and the first rib.

Mr. R. J. GODLEE read an account of two cases of Simple Fracture of the Skull in Infants, followed by the Development of a Pulsating Tumour, and showed some drawings and specimens in illustration. The first case was a female infant, eight months old, that was brought to the hospital the day after a fall of fourteen feet on the side of the head. There had been no unconsciousness or external bleeding at the time; she had vomited shortly after. When seen there was a large hæmatoma over the right parietal bone, and there was almost complete paralysis on the left side of the body; the reflexes were absent on the left side. There was at first some difficulty in swallowing. On the fourth day right-sided convulsions occurred. Next day the paralysis began to improve and the swelling also gradually to disappear. At the end of about a week pulsation was first noticed in the swelling. Three weeks after the injury the hæmatoma was increasing in size and was aspirated, 7½ oz. of fluid being removed; the fluid was muddy-looking, alkaline, and contained a few corpuscles. In three days another small aspiration was performed, and two days later the swelling was opened, a large quantity of fluid similar to that already obtained came away, likewise some genuine pus. Death occurred next morning. At the autopsy the hæmatoma was found to extend the whole length of the parietal bone. In the middle of it there was a gap in the parietal bone half an inch wide with irregular edges. Brain matter could be seen through the gap, and it was ultimately discovered that there was a direct communication between the hæmatoma and the descending cornu of the lateral ventricle. On removing the bone the dura mater was found lacerated corresponding to the fracture in the skull, the brain was collapsed on the same side, and there had been a rupture of the temporo-sphenoidal lobe at the upper part that communicated with the interior of the brain as just described. There was extensive meningitis at the base, and arachnitis of the vault on the right side. Mr. Godlee drew attention

to the character of the fluid that had been drawn off; there was evidence that it was partly inflammatory and in part derived from the cerebro-spinal fluid. He also referred to the want of correspondence in gravity between the symptoms and the damage done to the brain. The second case was that of a male infant aged five months that came to the hospital after having fallen on to his head from a height of eight feet. He was cold and collapsed, and had not vomited; there was a hæmatoma extending forwards from the back of the head on the right side. Convulsions appeared a few hours later, being mostly right-sided. The twitchings lasted some days. At the end of a week pulsation was observed in the tumour, and impulse on coughing. The temperature continued at or about normal, but the swelling increased in size, and on the thirteenth and fifteenth days it was aspirated. Very little fluid was, however, drawn of, and the child's general condition remained the same. At the end of two months the child was allowed to be taken home, a shield having been provided to protect the still pulsating swelling. Shortly after this the child was taken to another hospital, where he died in the course of a few days with symptoms of meningitis. On examining the right parietal bone, there was found a large irregular opening, running obliquely downwards and forwards, measuring three inches long by three-quarters of an inch across. At each end of the opening the bone was fissured for nearly an inch. The margins of the opening were very thin, and the absorption of bone seemed to have taken place chiefly at the expense of the outer table. The bone was everywhere very thin, but there were no spots of cranio-tabes. On the other parietal bone there was an indentation corresponding in shape and size with the above opening; the bone was very thin, quite membraniform, in this region. The symmetry of the lesion of the bone suggested that the child's head might have been squeezed in some way, but there was no history of this. Mr. Godlee pointed out that in the infant the bones of the skull were very flexible, and that they were united by sutures which were soft and permitted of a considerable amount of movement, and further that the dura mater in young infants was firmly attached to the bones. He thought that these facts would help to explain the different results of direct violence to the skull in the child and in the adult; in the former the force being almost altogether spent upon the part struck.—Mr. THOMAS SMITH said that he had written a paper for the St. Bartholomew's Hospital Reports dealing with this subject. He had found that the fracture was much more common than we suppose, and he was certain that he had overlooked cases in the past, probably, like others, putting them down as common cephalhæmatoma. Recently a professor of Ohio had published in the *American Journal of Medical Sciences* a paper entitled Cephalhydrocele, which treated of these cases. The tumour generally communicated with the lateral ventricle, and occurred in young children mostly under the age of four years. In addition to the eighteen or nineteen cases quoted by the American journal he had contributed in his paper a few others. The history of all of them was very much the same. A fall seemed to cause a simple fracture of the vault of the skull, and a pulsating tumour developed. This tumour when punctured gave out a serous fluid. In a large number of cases operative interference in the way of setons or punctures or injections with iodine were practised, usually with a fatal result. The employment of a fine trocar seemed to be least dangerous. It was plain that there must have been removal of bone in some sort of way, and Mr. Bowlby suggested that some injury to one of the ossifying centres of the skull would best explain the large size of the hole in the vault. The margin of the hole was worm-eaten in appearance, and this could not be due to pressure from within the skull. In most cases the tumour communicates with the interior of the ventricle, as Mr Lucas had said. Mr. Lucas had recorded two cases and Mr W. Haward one, and a fourth was to be found in Erichsen's Surgery. These were the only cases recorded up to the present time in England. The bony margin of cephalhæmatoma was not present in these cases. Again, the pulsation might be feeble, and so the diagnosis was sometimes mistaken for cephalhæmatoma. The presence of sugar in the fluid was probably due to irritation, and not to the presence of mere cerebro-spinal fluid.—Mr. C. LUCAS referred to the cases which he had recorded in the Guy's Hospital Reports. In the first case the fluid in the tumour was examined by Dr. Stevenson, and found to be cerebro-spinal fluid. The child died two years after the tapping, and the signs of acute meningitis existed at the base of the brain. The second case was still living. The third case died of erysipelas. The ventricle was seen running up to the tumour in the scalp. Wherever cerebro-spinal fluid was present the ventricle was always injured.—Mr. VICTOR HORSLEY said that, from an unpublished experiment on a monkey's brain, he concluded that cerebro-spinal fluid may be present in such tumours without injury to the lateral ventricle. He had removed the ascending parietal convolution in a monkey. Later on, in completing a further removal of the cortex, he found it necessary to remove the whole parietal bone. One week after this operation a pulsating tumour developed, which was treated by aspiration; the fluid was found to be cerebro-spinal fluid, and the tumour was aspirated a second time, after which it did not reappear. In this case the fluid was secreted by the arachnoid and accumulated beneath the shrunken dura mater, and was prevented by adhesions of delicate soft connective tissue from passing (on the view of Azel Key and Retzius) away towards the base of the brain. In this way it was possible for a pulsating collection of cerebro-spinal fluid to be formed without the ventricle being injured. Bergmann had collected five cases of this fracture in the child; all occurred in children under three years of age, and there was a decidedly elongated fissure of the skull in each.—Mr. A. A. BOWLBY thought that a possible explanation of the size of the fissure might be found in the fact that the bone itself was growing at the time of the injury, and grew away from the fracture owing to the continuous pressure of fluid.—Mr. WARRINGTON HAWARD referred to the case which he had published. It was one of simple fracture in the frontal region, with the characteristic subsequent changes. But very little blood had been extravasated at the site of fracture.—Mr. W. HULKE referred to a recent case in which the fracture occurred in the parietal region, and was followed by the formation of a pulsating swelling. In his note-books he had two or three other similar cases, and the contents of the tumour were proved by puncture to be cerebro-spinal fluid.—Mr. R. J. GODLEE, in reply, said that on the question as to whether it was necessary to have a wound of the ventricle, Mr. Horsley's explanation was exceedingly interesting. He spoke of the case of a child with fracture in the frontal region, which was compound; the wound behaved healthily, and there was no escape of cerebro-spinal fluid. He did not think that the size of the hole in cases of cephalhydrocele was due to arrested development, for the case only lasted two months, which period was not sufficient for the bones to have grown so much as to favour Mr. Bowlby's explanation.

The following card specimens were shown:—Dr. Norman Moore: Hæmorrhage into the Substance of the Liver with Rupture of the Peritoneal Coat in a case of Anæmia. Mr. Lockwood: Rudimentary Abdominal Ribs. Dr. Silcock; Tubercular Disease of the Epididymis. Dr. Charlewood Turner: Aneurysm of the Aorta opening into the Œsophagus and Aneurysm of Sinus of Valsalva with Abnormal Coronary Arteries. Dr. Herringham: Two specimens of Calcareous Change in the Spinal Membranes. Mr. Poland: Synostosis of Foot. Dr. G. N. Pitt showed a recent specimen of the Kidneys and Liver in an Infant with Syphilitic Lesions.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

AT the meeting on Dec. 5th, Mr. Frederick Lawrance, M.R.C.S., President, in the chair,

Mr. SPENCER WATSON read a paper on a case of Sympathetic Ophthalmia. The patient, a farm labourer, injured the right eye, and went about his work, applying only a wet linen rag to it. Fourteen days later the left eye became sympathetically affected. No active treatment was employed till his admission into the South London Ophthalmic Hospital six weeks after the accident, when local cold applications and mercury internally were employed to reduce the swelling of the eye and orbit. Enucleation was performed two months after the accident. The ciliary processes, iris, and capsule of the lens were found matted together, and the pupillary area occupied by a firm membrane. There were traces of neuro-retinitis. The lens was *in situ* and the vitreous scarcely altered. The sympathising eye had retained the same amount of vision as before the operation, and tension, though at times high, was normal. The patient could read No. 16 Jaeger. The main features of

treatment throughout had been mercury, eserine drops, blisters to the temple, and exclusion of light. The author remarked on the carelessness of the patient in using the eye without a shade. The ultimate result was conjectural, but probably in one or two years an operation for opening the pupil, and perhaps removing the lens, would be required. With the sight in its present state, expectant treatment would be followed.—Mr. J. R. LUNN recommended early enucleation of the injured eye.—Dr. ALDERSON thought the name "sympathetic ophthalmia" confusing, owing to its likeness to the term "sympathetic irritation." Great care should be taken to observe the early symptoms, which were generally in the iris.—Mr. SPENCER WATSON, in reply, said the disease might come on months, or even years, after the injury to the other eye. He agreed with Mr. Alderson as to the value of blisters.

Mr. R. F. BENHAM read a paper on the Uses of Sulphide of Calcium. The author remarked that in his opinion very many of the failures in the use of this drug were due to too sparing administration.—Dr. RINGER drew the attention of the profession to this drug in a paper in THE LANCET, 1874, vol. i., in which he stated that sulphide of calcium possessed the power of arresting and preventing suppuration in such cases as boils, carbuncles, scrofulous and glandular enlargements, and in many skin diseases. After reading many cases treated by various practitioners, the author remarked on the number of unsuccessful cases, and said the quantity given had been too small. A dose of one-sixth of a grain might cure in one case, but not necessarily in another. He regarded the appropriate dose for an adult to be one grain in pill three times a day; but if after, say, a week no improvement occurred, he made an increase of one grain a day or every few days, until eight grains daily were reached. The dose which had hitherto been regarded as poisonous he found did not produce alarming toxic symptoms; secondly, only a small quantity of the drug taken is decomposed in the alimentary canal to form H_2S; and last, but not least, from the ordinary dose he did not find anæmia produced, but, on the contrary, even when six or eight grains daily were given general improvement in health resulted even when the drug failed in curing the symptoms for which it had been administered. The author maintained that the physiological action of the drug is not due to its conversion into H_2S in the organism; it could not be that only a small portion is absorbed and the remainder passed off unchanged, for if so why should a large dose effect a cure when a small one failed? The author preferred giving the drug in pill, as by this means the taste is unobserved. Mr. Benham read notes of a series of a large number of cases treated with success, and also recommended the drug in phthisis, typhoid, and small-pox.—The PRESIDENT had found the drug cause intestinal derangement; he had found it useful in gum-boil.—Dr. JAMES THOMPSON found one-tenth of a grain the safest dose to begin with.—Mr. MAITLAND THOMPSON had not found it useful in strumous glandular affections.—Dr. BENNETT asked if the drug resembled turpentine in causing more irritation in small than in large doses.—Dr. HUGGARD and Mr. EDWARDS referred to non-success with the drug.

Dr. THUDICHUM read a paper on "Inflammation, Abscess, and New Growths of the Ethmoid Cells." Inflammation he described as acute and chronic, as simple or dyscratic. The specific diseases lead to the chronic form with acute outbursts. In the latter the symptoms become very precise, and yield the data by which to diagnose the milder cases. Pain between the eyes, loss of smell, excess of nasal secretion, swelling of the glabella, swelling and discolouration of eyelids can mostly be distinguished on one or both sides. Hypertrophy of the ethmoid cells leads to obstruction of the upper nasal meatus. In such cases the author had removed the hypertrophied parts on both sides successfully with the electro-cautery. In other cases he had removed the middle concha on one side and thereby cured ozæna. The author next described some severe cases of abscess of the ethmoid cavities; these opened either into the nose, or on the upper eyelid or below the inner angle of the eye without involving the lacrymal apparatus. He further described new growths, myxomatous as well as cancerous, proceeding from the ethmoid cells, and the manner in which they had in several cases produced blindness of one or both eyes. He described a new apparatus for flushing the nose in cases where the septum was perforated or destroyed, and in which, therefore, the one-current douche originally described by him was not applicable.—Mr. SPENCER WATSON thought loss of smell a very valuable diagnostic sign. Sulpho-carbolate of soda was a useful drug for lotions and sprays in these cases.—Dr. CAMPBELL POPE and Mr. BENHAM related cases where the disease extended to the lacrymal apparatus.

Mr. KEETLEY showed cases of Hernia Cerebri, Syphilis of Nose, MacEwen's Osteotomy, &c., and Mr. PERCY DUNN showed Morbid specimens of the parts after Gastrostomy, &c.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

A GENERAL meeting of this Association was held on Wednesday last, Surgeon-Major Evatt, M.D., President, in the chair. The number of members of the Association now exceeds sixty-two. The following gentlemen were elected members of the Association:—Dr. Clement Dukes, Mr. E. S. Pattison, Mr. Shirley Murphy, Mr. O. H. Fowler, Mr. H. Lockwood, and Dr. Fergus.

The code of rules for the prevention of infectious and contagious diseases in schools was taken as read. On the motion of Dr. Alder Smith, seconded by Dr. Fuller, it was proposed that the code of rules which had been sent round to all the members of the Association should be put to the meeting and passed *en bloc*. The proposal was unanimously carried. The meeting next proceeded to consider the various sections of the code *seriatim*. It was decided at the close of the meeting, which lasted nearly three hours, that the code of rules should be published by Messrs. Churchill. The full title of the forthcoming book is "A Code of Rules for the Prevention of Infectious and Contagious Diseases in Schools, being a series of resolutions passed by the Medical Officers of Schools Association." The first suggestion for alteration came by letter from Mr. Paget, of Kendal, who proposed that in the title-page of the code of rules the words, "not being public elementary schools" should be added. This addition was not approved by the meeting.

In the section headed General Hygiene, Dr. Fergus of Marlborough proposed that the clause on drainage, relating to the trapping of the main sewer at its junction with the drainage system of the town, would be improved by the addition of the words "and ventilated" after trapped. This addition was agreed to without discussion.

Considerable discussion took place on the seventh clause, in which Mr. Shirley Murphy, Dr. Jones of Epsom, Dr. Alder Smith, the President, and Dr. Briggs took part. It was finally agreed that the clause should read thus: "That if a cesspool must exist, it be placed no nearer to a dwelling-house than fifty yards; that its ventilation be effected by pipes of sufficient height, and opening in a safe position, not less than four inches in diameter," &c. The eighth clause was also slightly modified, and read thus: "That all overflow, rain water, and waste-pipes discharge in the open, near properly trapped gratings."

With regard to section 3, relating to the undivided medical responsibility of the medical officer of a school, much time was spent in discussing the relations of partners in a medical firm. Dr. Briggs, Dr. O'Brien Jones, Dr. Fuller, Dr. Bridgewater, Dr. Statham, Mr. Holderness, Dr. Shelly, and others, spoke on the subject. It was finally declared by a show of hands that the original clause should stand. Therefore one medical man, and one only, shall have the entire school under his daily care and medical supervision.

Dr. Armstrong suggested that the medical inspection of the school premises should be made at least every fortnight instead of every month. This proposal was negatived by the meeting.

The fourth clause in section 3 was altered at the instigation of Dr. Armstrong so as to read as follows:—"An annual return of school sicknesses to the governing body of the school from the medical officer is very desirable." Dr. Fuller said that a daily return was made to the head master at St. Nicholas College, Lancing; and Dr. Alder Smith said that he made a weekly report at Christ's Hospital.

Dr. Clarke, seconded by Dr. Armstrong, succeeded in altering clause 2, section 5, so that the medical officer should occasionally visit the dining-halls and kitchen, so as to satisfy himself that the food was properly served and cooked. Dr. Holderness said that such a course would be utterly impracticable at Eton. Dr. Shelly proposed that the original clause should read, "food supplies, cooked and uncooked."

Dr. Alder Smith said that with regard to the infirmary,

Mr. Paget had written that he objected altogether to a general infirmary. Dr. Briggs thought it was unwise to have a general infirmary, for infectious and ordinary cases might get mixed up. After some discussion, it was agreed that the original clause should stand.

Dr. Soper, Dr. Jones, and others made some remarks on the subject of revaccination, but no alterations were made in the section referring to this question.

Different opinions were expressed on the duration of the quarantine after exposure to infection. Dr. Clement Dukes, of Rugby, thought that eight days were sufficient for scarlet fever, and Dr. Fergus suggested seventeen days.

The following "quarantine times" after exposure to infection, provided thorough disinfection be carried out on the pupil's return to school were ultimately decided upon:—

Diphtheria, 12 days; scarlet fever, 14 days; measles, 16 days; German measles, 16 days; chicken-pox, 18 days; small-pox, 18 days; mumps, 24 days; whooping-cough, 20 days.

Clause 3 in section 14, relating to infectious disease in masters' houses, was, after being discussed by Dr. Dukes, Dr. Bridgwater, Dr. Clarke, Dr. Smith, and Dr. Holderness, agreed to be read as follows:—"The master or officer would be advised to undergo thorough personal disinfection before resuming work in the school, and should live away from his house as long as infection continues, especially if the case be one of scarlet fever, diphtheria, or small-pox."

Several gentlemen discussed the question of disinfecting letters and other possible modes of communication between the infectious wards and the outside world. The sixth clause in section 15 was allowed to be read thus:—"All letters, if allowed at all, coming out of the infectious wards, should be disinfected before they are posted."

Section 2, clause 16, was modified to read thus:—"Notice should at once be *privately* given to the matrons (in the event of an outbreak of infectious disease) or others in charge of the pupils, to carefully watch for any symptoms of fever, and to send any child looking ill to the infirmary, and report the same at once to the medical officer."

The clause in section 17 relating to the disinfection of the medical officers' clothing was expunged as an unnecessary instruction. The last sentence in the following clause was cut out for a similar reason. This clause would then stand thus: "It is a good plan to keep a large mackintosh outside the entrance to the infectious ward, near some volatile disinfectant, and for the medical officer to put it on before he enters; he should also take the ordinary precautions against the disinfection of his person."

As regards section 21, dealing with the question, "When may a pupil who has had an infectious disease go home or rejoin the school?" it was resolved that the clause dealing with scarlet fever should be altered to run thus: "Scarlet fever in not less than six weeks from the date of the rash, if desquamation have completely ceased and there be no appearance of sore-throat." The original clause included "and no albuminuria," but it was argued by Dr. Briggs and others that albuminuria might persist for so long a time as to render detention undesirable and even injurious for the patient.

In the clause referring to purulent ophthalmia Dr. Alder Smith proposed, at the suggestion of Mr. Henry Power, that the words "or inner surface of the lids are found to be quite free from granulations:" this addition was concurred in. The appendices were assented to by the meeting almost without exception; the only alteration made was in question 5, which asked, "Is the child subject to any special form of illness?" It was agreed that the words "including incontinence of urine" should be appended.

The President referred to the great labour and time which Dr Alder Smith had expended in drawing up this code of rules, and felt sure that the Association would accord a special vote of thanks for these services. After some discussion on the method of publication of the code the meeting broke up.

ACADEMY OF MEDICINE IN IRELAND.

THE opening meeting of the Surgical Section was held on Friday evening, November 14th, at the College of Surgeons, Dr. Bennett, President, in the chair.

The PRESIDENT delivered an inaugural address, in which, having referred to the death of Prof. Stannus Hughes and Dr. B. Wills Richardson, he dealt with the Cause and Treatment of Congenital Dislocation of the Hip.

Dr. BALL read a paper on a case of Melanotic Sarcoma of the Rectum removed by operation. The patient, a fairly healthy-looking woman, aged sixty years, stated that eleven months before coming under observation she had noticed a pile which had been removed by operation, after which she remained free from rectal symptoms for four months. She then suffered from increased difficulty in evacuating the bowels. A slight discharge of bloody mucus appeared, and she became conscious of a hard tumour in the rectum, which partly protruded on stool. These symptoms continued to increase, and on admission defecation was difficult and painful, the pain being referred to a point immediately above the symphysis pubes. Upon examination the anus appeared normal, and the sphincter was not unduly relaxed. About an inch from the anal verge, on the anterior aspect of the rectum, two distinct and tolerably hard tumours could be felt, evidently implicating the mucous membrane; and by pressing the finger well up the superior limits of both could be readily made out, and below them a smaller mass was to be felt. The rest of the rectum appeared healthy, and no abnormal adhesion of the bowel to the other pelvic vessel was indicated. The mass was extirpated by the usual method on November 1st, a free posterior incision being made to give room. Corrosive sublimate solution, 1 to 2000, was the antiseptic used, and the wound was left open. The after-progress of the case was afebrile and satisfactory. The bowels moved for the first time on the fourth day, and the patient had complete control over the evacuations. The piece removed measured about three inches in breadth and two and a half inches in length, and consisted of the anterior two-thirds of the circumference of the bowel. There were two principal growths, separated by about half an inch of mucous membrane and equidistant from the anus. The larger had a depression in the centre, and was of a whitish colour; the other was black on the surface and spherical in shape. Below the two principal tumours a smaller nodule, also black in colour, was to be seen. A section carried through the two larger growths showed that the lighter coloured one was of the same hue throughout, except where a small blood-clot existed in the interior; but the second was of a sooty black colour, as seen on section. The shape and arrangement of cells were similar in both tumours, being those of a typical sarcoma. The cells were round, ovoid, or even spindle-shaped, with large nuclei, and in some portions resembled a form of alveolar sarcoma. In the larger one there was a very slight amount of pigment, but in the smaller pigmentation was extreme, some of the cells appearing as large masses of blackish material, while others had dark granular material, more sparsely scattered in their substance. In the portion of mucous membrane between the two growths the glands were much atrophied and surrounded with symphoid tissue.—Mr. CROLY mentioned that he had had under his care a considerable number of cases of cancer of the rectum. In the majority of these cases pain had not been absent. The situation of the disease accounted for the presence or absence of pain; for instance, when the diseased mass went towards the bladder it gave rise to greater disturbance than if it went backwards towards the hollow of the sacrum. With regard to operative treatment, cases for colotomy were one set and those for excision of the rectum another. Where the finger could not be got above the diseased mass excision was hazardous, and the fact ought to be put before the patient that if the disease extended high up excision was attended to with considerable risk, while colotomy was merely a palliative operation.—Dr. PUREFOY, having had under observation during the past three or four years two or three cases of malignant disease, referred to one of them as being interesting in respect to the locality of the pain. About eighteen months ago an unmarried middle-aged lady consulted him for a very distressing pain in the left hip, and said she felt a hard lump close to the anus. After careful examination, and as he was about to give up in despair, on making deep firm pressure close to the anus in the left ischial fossa his finger impinged on a hard nodule. He found the whole tube of the gut occluded by large hard nodules situated in the ball of the gut and projecting considerably into the vagina. She made no complaint of pain in defecation. Her sister had died of malignant disease in the same part of the body. There being no difficulty in the passing of the fæces, he did not suggest colotomy. About a month or six weeks afterwards the recto-vaginal septum became perforated, the fæces escaped, and the patient died in three months. The interesting point was her complaint of pain in the left hip extending down the leg.—Mr. HAMILTON said the insidious nature of cancer of the rectum was such that it might go on for a considerable time

without developing symptoms or attracting attention to the real nature of the disease, and hence so many cases were treated for obstinate constipation of the bowels, &c., even for urinary trouble, because of the close sympathy of the bladder in the early stages of the disease. The cases justifying excision of the rectum were few in number, taking into account the health and age of the patient and the extent of the disease. Linear rectotomy was probably more desirable than colotomy.—Dr. HENRY KENNEDY pointed out that extensive disease might go on in the uterus without any suffering, while slight disease would be attended with great pain.—Mr. THOMSON held that if they could perform an operation which would remove, at least for some years, a disease like cancer, it would be not only of the greatest possible advantage, but an advance in surgery to boast of. There were, however, at least two dangers—one, a very severe stricture occurring at the orifice in the anus, and the other incontinence of fæces, either of which left the patient almost as bad as before. He preferred colotomy to linear incision, or to the method of scooping, neither of which he considered to be of a surgical character. In return for enlarging the opening of the rectum and removing the obstruction to the passing of the fæces, what was given was a wounded surface, the base of a mass of malignant disease. In scooping out, the whole of the disease was not removed either, and a wounded or bruised surface, sarcomatous or whatever it might be, remained for the fæces to pass over it. No doubt colotomy had the disadvantage of being merely palliative. The true lines were laid down by the surgeon who advocated the complete division of the colon, suturing the lower end of the upper part of it to the wound in the abdomen, inserting the upper end of the rectum into this, stitching the walls together, and finally removing the part altogether.—Mr. WHEELER believed he was correct in saying the author of the paper had stated the case which he had operated on was not yet healed; but he did not gather that it was advocated to scoop or break down the cancerous masses in the rectum.—Mr. W. THORNLEY STOKER observed that there were two kinds of pain in connexion with cancer of the rectum—a pain inherent in and peculiar to cancer, and a pain attended with the development of cancer to such an extent as to cause obstruction of the bowel. There was but little, if any, pain until the disease caused obstruction.—Dr. BALL replied, and the Section adjourned.

Reviews and Notices of Books.

Insanity and Allied Neuroses; Practical and Clinical. By G. H. SAVAGE, M.D. London: Cassell and Co. 1884.
Lectures on Mental Diseases. By W. H. O. SANKEY, M.D. Second Edition. London: H. K. Lewis. 1884.

DR. SAVAGE'S book is a compact volume of 540 pages, forming one of Messrs. Cassell and Co.'s series of special monographs. It is written in a somewhat popular style, and the subject is treated in an interesting manner. Dr. Savage has avoided the besetting sin of writers on this subject, and has not invented a new classification. His grouping of insanity is practical and convenient, and the observations on each group are acute, extensive, and well arranged. In writing of the influence of heredity, the author states that cases are frequent in which sane children are begotten in the intervals between attacks of insanity. It is doubtful whether the author intends by this to imply that such children have an immunity from hereditary predisposition, or are simply born without mental defect. Dr. Savage would not appear to dwell with sufficient emphasis on the danger of religious excitement in the development of insanity, and appears to miss the opportunity of impressing his readers with the risk which neurotic persons run in giving way to such excess. The chapter on Hypochondriasis and Melancholia is amongst the most interesting in the book, cases being given illustrative of the relations of this form of disorder to the various organs. Melancholia in its various forms is also treated in a singularly graphic manner, and the same may be said of the division devoted to General Paralysis. It is to be regretted that Dr. Savage, with his extensive experience of the pathology of this disease, has not treated this branch of the subject more fully. In conclusion, the opinion may be expressed that this work will be found to be practically useful to the general practitioner, and that its suggestiveness will make it worthy of a careful perusal by all who are specially interested in the treatment of the insane.

In the second edition of Dr. Sankey's book there is so much that is original as practically to constitute it a new work. The first part of the volume is devoted to the consideration of the physiology of the mental functions, and is a very able *résumé* of the views of the best writers and observers. Mental diseases are ranged by the author in two divisions: (*a*) in which the mental symptoms are primary or idiopathic; (*b*) in which they are secondary or symptomatic. The first division is subdivided into *pathological*, which includes ordinary insanity and general paresis, and *developmental*, embracing idiocy and senile decay. The second, or symptomatic division, includes epileptic insanity, alcoholism, spinal diseases, and organic cases. This classification is eminently simple and practical. Dr. Sankey still strongly insists on the necessity of regarding melancholia as a first stage of ordinary insanity, and mania as the second. A chapter is usefully devoted to deprecating the continued use of a large number of terms, applied to so-called varieties of insanity, which are derived from some prominent symptom, presumed cause, or modification of the course of the disorder. The chapter on the Pathology of General Paresis is especially interesting, particularly in the table which contrasts the pathological alterations found in general paresis with those found in ordinary insanity. From this comparison the conclusion is drawn that the vascular system is much more affected in the former than in the latter. The book bears evidence of great independence and originality of thought, and the author's views are stated concisely and forcibly. It constitutes an important addition to medico-psychological literature, and will be found of especial value as a class-book.

A Treatise on the Theory and Practice of Medicine. By JOHN SYER BRISTOWE, M.D. Lond., LL.D. Edin., F.R.S. Fifth Edition. London: Smith, Elder, and Co. 1884.

OF all the numerous text-books of medicine now at the disposal of English reading students there is hardly one which deals with the whole range of subjects so scientifically and at the same time concisely as this work of Dr. Bristowe, which has now reached the fifth edition. It is clearly the outcome of the author's personal experience and extensive study, and such pains have been bestowed by him to keep his subject abreast of the advancing knowledge of the day that if a student were to confine his systematic reading to one book alone, we might safely refer him to this. So far as we are enabled to judge, there is maintained through all its chapters the desire to present a clear and comprehensive account of disease, so that it is not possible to point to one section as outweighing any other in the style or completeness with which the subject is treated. At the same time the work is far removed from the *vade mecum* style of literature, which exerts so cramping an influence upon the student's mind. For these and other reasons the treatise is one which will have a more permanent value than a text-book usually has; for the practitioner will find it as useful as does the candidate for a medical degree. We have heard it said that, excellent and truthful as Dr. Bristowe's work is in pathology and diagnosis, it is lacking in the very essential subject of therapeutics; but we confess to be unable to concur in this opinion. The author has had a long career as physician to a large London hospital, he has studied all forms of disease, and is most fully acquainted with their natural progress and results. If anyone is entitled to speak with authority upon the effects of

remedial agents in arresting the course of a malady, or in alleviating its risks, surely Dr. Bristowe is, and it is just because he wisely restrains himself from the temptation to parade prescriptions and formulate particular lines of treatment where general principles alone can be submitted that the notion of a deficiency in practical measures has arisen with respect to this work. We all know that the science of therapeutics is very far from being exact, and he is the wisest physician who, recognising this and knowing the course of disease, refrains from suggesting or directing particular measures which can only have a partial and incomplete application. The rapidity with which new editions of this work succeed one another leaves the author but little time for revision, but he has done much to the present edition in this respect and in the addition of new chapters, including one on Acute Rickets, showing how fully alive he is to the progress of medical research.

La Hijiene de la Escuela. Por RICARDO DAVILA BOZA. Pp. 143. Santiago: Cervantes. 1884.

IT is satisfactory to those who take an interest in the welfare of the rising generation to find the study of the sanitary condition of schools extending into foreign lands. The work now before us is a contribution to that subject from the Republic of Chili. It does not profess to bring forward any new views, but is apparently a careful digest of the best received opinions brought together for the instruction of those on whom the construction, arrangement, and management of schools devolve. It treats of the construction and general arrangement of the schools, the fittings and school furniture, the system of teaching, the internal management, and the personal hygiene. In the construction of the schools there is one provision to which we take very strong exception—that of a dungeon or solitary cells, in which refractory pupils may be locked up for several hours. Our author says: "It is a very general custom to impose upon the pupils of the schools, besides other punishments, that of the dungeon or confinement in a solitary cell for several continuous hours. As there is no objection to offer to this species of punishment, always provided it is restricted within certain limits, it is necessary to provide in the school building an appropriate place in order that its application may not degenerate into a cause, however slight, of loss of health." In the requirements of these cells there is no mention of windows, though provision is made for ventilation, so that we infer they are intended to be "black holes." The system of locking up children by themselves for some hours as a punishment is much to be deprecated, but with the additional terror of darkness it is simply disgraceful cruelty, and might be followed by most serious consequences. We would call the attention of Señor Boza to the subject in the hope that he may take it up with a view to the abolition of so objectionable a punishment. The book is one deserving of commendation, and appears well adapted to spread sound views of school hygiene among the Spanish-speaking populations; it is therefore with regret that we feel bound to protest against the author's views on the important subject of school punishments.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

ON Jan. 2nd, at 4 P.M., a deputation from the Association of Members of the Royal College of Surgeons was received by the President and Vice-Presidents of the College in the council room of the College.

Dr. COLLUM, Chairman of the Association, opened the proceedings with a few remarks on the object of the deputation and on the nature of the Association. One of the grievances of which the Members of the Association complained was the circumstance that the executive of the College entirely ignored the existence of the Members of the Royal College. Considering what a large proportion of the funds of the College was derived from its Members it seemed unjust that a body, about 15,000 strong, should be overshadowed by the body of the Fellows, numbering only 1200. The action of the London College was such as to drive the children of medical men in its vicinity, as well as colonial students, to Scotland and elsewhere, where degrees could be obtained at much less cost than a diploma which gave the owner no better title than that of "Mr." It should be borne in mind that the Members of the College existed long before the Fellows, and he contended that the former had a right to be directly represented on the Council of the College.

Mr. JOSEPH SMITH, M.R.C.S., Vice-Chairman of the Association, said that the Committee of the Association of Members of the Royal College of Surgeons had deputed him to lay the following resolutions before the President and Vice-Presidents of the Royal College of Surgeons. First: "That the Council shall consist of twenty-four members and the president. That the election of members of Council shall take place every three years; and that the duration of office shall be three years. Each member of Council may be eligible for further re-election for a term of three years; but no member who has served the full term of six years shall be again eligible until after the lapse of three years from the time of his last holding office." Secondly: "That the members of Council be elected by the Fellows and Members of the College equally—that is, half by the Fellows and half by the Members of the College." Thirdly: "That voting take place personally at the College, and also by voting papers, to be sent to each Fellow and Member of the College in the United Kingdom whose names are on the Register." Mr. Smith then remarked that these were the main and important points which the Committee desired to place before the Council of the College with a view to inserting them in the new Charter. The Association felt that their demands were not only equitable but just. It was a marvel that the great body of the Members of the College had remained quiet so long. The Association already numbered 1000 adherents, and would no doubt before long be largely increased. Representation was the principle at which the Association aimed. An important provincial Medical Association had recently passed the following resolution:—"That no alteration in the Charter of the Royal College of Surgeons would be deemed satisfactory unless it made provision for the election of the Council by the Members and Fellows unitedly, and for the election of the President by the Council." Mr. Smith referred to the income of £20,000 enjoyed by the College, and said that nearly £15,000 was contributed by the Members. A diploma was all the return the Members got. The President was but the President of the Council of the Royal College, and not the President of the Royal College of Surgeons. The Association had approached the Council in no spirit of revolution, but it felt that if its demand were refused the Secretary of State for the Home Department would be approached and the case laid before him as a last resource.

Mr. J. BRINDLEY JAMES said that he had received no notice whatever of the general meeting of the Fellows and Members held in March last. He complained that the Members of the College were completely overlooked, and that they were never invited to the soirées given by the College. If the Council refused to listen to their just demands, extreme measures would have to be resorted to.

Mr. OUTHWAITE maintained that proportional representation of the Members of the College on the Council was but just and fair. Many men of ability were prevented from taking the Fellowship solely on the ground of want of time or money.

Mr. COOPER FORSTER, the President, said that the Vice-Presidents and himself simply represented the Council, and so anything he might say must be regarded merely as an individual opinion. If the resolutions were drawn up and sent as soon as possible, no doubt they would receive consideration at the hands of the Council. It should be said that the conversaziones were given by the President or Conservator, and solely at his expense; invitations were given, as a rule, only to their immediate friends, whether Fellows or Members, or laymen.

It was agreed that the Association of Members should be informed as soon as possible of the date fixed by the Council for the application to the Home Secretary for the new Charter.

Mr. JOSEPH SMITH then thanked the President and Vice-Presidents for the kind manner in which they had received the deputation, and the proceedings terminated.

THE LANCET.

LONDON: SATURDAY, JANUARY 10, 1885.

AT the meeting of Convocation of the University of London on the 6th inst., a resolution in reference to the new Teaching University scheme was moved by Mr. ANSTIE, Q.C., seconded by Dr. PYE SMITH (in the absence of Dr. WILKS), and carried unanimously. The terms of the resolution were, "That a special committee of forty members be appointed to consider the proposals lately published by the Association for Promoting the Establishment of a Teaching University in London, and to report thereon to Convocation; and that it be an instruction to the committee to take the necessary steps for summoning a meeting of Convocation at the earliest convenient opportunity." The committee which was elected was a most representative one, including graduates from every faculty—arts, science, law, and medicine—and safeguarding the teaching interests as well as what we may call the more traditional element of the University. As the meeting was subsequently adjourned to February 3rd, we may conclude that the report will be brought up and considered on that date. A considerable discrepancy of opinion existed amongst those who spoke to the resolution as to whether a Teaching University would strengthen or injure the existing institution, but it was evidently felt that the question could no longer be ignored, and that some steps would have to be taken either to embrace and, if possible, incorporate the rival body as soon as its scheme was fully launched, or to obstruct its progress at every turn. The names of the committee form a sufficient guarantee that the new scheme will have due consideration, and that no measure will be taken to hinder its normal development. The real question at issue is, whether the University of London can in any way accede to the views of the promoters of the new University, or must the two bodies necessarily remain apart and each go on with its own work in entire disregard of the existence of the other? The answer to this question depends on that which must be given to another question—namely, what are the founders of the new Association really striving to obtain? Their report is so vague and chaotic that we cannot be sure that they are unanimous in their main ideas and all anxious for the same object. Will the University of London be asked to refuse its degrees to students who have had no collegiate training? and, if it declines to do so, will the promoters of the new University apply to Parliament for a Charter to enable them to examine and confer degrees upon those students only who have been taught in their colleges and affiliated schools on a system of education laid down by themselves, and over which they are to have absolute control? We cannot imagine, much less comprehend, a Teaching and Examining University as proposed, and a mere examining board for the British Empire like the present University, existing under the same roof, or even side by side, each following its own line. If our question be answered in the affirmative, it is evident that King's and University Colleges and the hospital medical schools are the only bodies in the metropolis in which such a course of general and technical education is given as will justify an application to Parliament, and these must become the basis of the new University, and the nucleus around which any other institutions are afterwards arranged. If, on the other hand, the new Association merely seeks to modify the composition of the Senate of the existing University by adding professors and teachers, and representatives of learned bodies, such as the Inns of Court, the Royal Academy, and the authorities of the British Museum, the new scheme is hardly worth the time and trouble which have been devoted to drawing it up. We speak thus plainly, because the recent letters of Professor LANKESTER and Sir GEORGE YOUNG in *The Times* disclose a great divergence of opinion in the committee on this point. Professor LANKESTER, in demanding a University on the lines of the Victoria University, has a very clear conception of what is wanted, whilst Sir GEORGE YOUNG is only following an *ignis fatuus* in endeavouring to bring together, for any useful purpose, bodies with such different objects as the University of London, King's and University Colleges, the Inns of Court, the Law Institution, the hospital schools, the Royal Academy, the British Museum, and the Institute of the City Guilds at South Kensington, and then calling the combination a University.

The position of the London medical schools must be clearly understood. The University of London, by its ill-advised regulations and its infrequent examinations, as well as by the undue severity of its tests, has rendered it practically impossible for more than a small percentage of industrious medical students to obtain a degree whilst staying and studying in the metropolis. This places the London teacher at a disadvantage with his competitors in Scotland, Cambridge, Durham, and Manchester; for a degree is now a commercial article, worth so much money in the country, and the practitioner of the future is aware of its value, and is no longer content with the M.R.C.S. and L.S.A., or even L.R.C.P., of his predecessors. The University of London cannot meet this demand, and students flock to the other degree-conferring universities; it should, therefore, continue as a sort of superior examining board, and should give up all its restrictions on medical candidates and subject them to an examination test only, as is the case in the other faculties. A new body is required to grant degrees to average candidates on the same lines, and at the same standard as those adopted at other universities. If the Teaching University can, by a combination with the Colleges of Physicians and Surgeons, perform this office, the difficulties in metropolitan medical education will be speedily removed; but if, by becoming incorporated with the existing university it is prevented from undertaking this duty, the support of the hospital teachers will be at once withdrawn from it, and other means must be found to enforce their just claims. We feel that considerations such as these, as set forth in the speech of Dr. BARNES in Convocation, must come home to the medical members of the Committee, for, as will be seen by the following list, they are drawn from nearly every school in the metropolis, and are all active teachers. They are: Professor MICHAEL FOSTER (Cambridge); Drs. WILKS and PYE-SMITH, and Mr. HOWSE (Guy's); Sir J. LISTER, Bart., and

Dr. CURNOW (King's College); Messrs. SAVORY and POWER (St. Bartholomew's); Drs. BRISTOWE and ORD (St. Thomas's); Dr. BARNES (St. George's); Dr. RINGER (University College); and Mr. MORRIS (Middlesex).

No one will be surprised that the answer of the Council of the Royal College of Surgeons of England to the recommendations of the Association of Fellows has caused intense dissatisfaction. At a meeting of the Committee of the Association held on Tuesday last two resolutions were unanimously adopted: one expressing extreme disappointment and regret that the Council should have rejected some of the recommendations to which the Association attaches the highest value, or only accepted them with such qualifications as to render them practically "inoperative"; the other requesting that no steps should be taken by the Council towards obtaining a new Charter until the various alterations proposed or accepted by the Council itself, together with the recommendations of the Association of Fellows, shall have been submitted to a general meeting of Fellows and Members. Considering all that has happened, and the opportunities that the Council has had of gauging public opinion, the Committee of the Association would perhaps have been justified in adopting a more combative and offensive policy; but in giving the Council one more chance of abandoning an absurd and untenable position, the managers of the Association have furnished additional proof of their moderation. That the Council will ultimately be defeated is certain. Important and fundamental changes in the constitution of the Council cannot be much longer postponed. In no other institution of national importance would the members of the governing body be permitted to appropriate as fees a large portion of the income. But it would almost seem that at the College of Surgeons some of the members of the governing body only seek office in order to secure an examinership worth nearly £500 a year. To such an extent has this evil grown, that until a month ago eleven members of the Council were, as examiners, receiving about £5000 every year from the coffers of the College. With such temptations towards selfish considerations, no governing body so constituted can be impartial. With these attractions and inducements to preserve the *status quo*, it is perfectly intelligible that these gentlemen should be of opinion "that the government of the College should still be vested in the Council." It is possible that, if time and circumstance were propitious, they would, in accordance with this opinion, be also ready and willing to follow the example of the worthy lawyers of Serjeant's-inn and Staple's-inn, and sell the College to the highest bidder, and then divide the proceeds among themselves. Indeed, many of the members of the Council do solemnly believe they are the *owners* of the College, and are therefore at liberty to do what they please with their own. The time is come when this delusion should be dispelled, and the truth effectually forced upon the consciences of the members of the Council that they are at most only *trustees*, and accountable to those from whom their trust is derived.

THE return to England of one of the Special Commissioners sent out by the Home Government to undertake a scientific inquiry into cholera in India, and the publication of the Preliminary Report of the Commission, which we reproduced last week, may be taken as indications that the inquiry is closed, and that the full text of the conclusions arrived at will soon be submitted to the public. Awaiting that event any detailed criticism of the results obtained would obviously be unwarranted, but we may take it as sufficiently clear that our Commissioners have confined their researches almost exclusively to the doctrine promulgated by Dr. KOCH, that a particular form of micro-organism is specific to the disease; and that in submitting this doctrine to the test of research and experiment they are satisfied that it is unsubstantial. In the succinct paragraphs of the Preliminary Report it is explicitly set forth that the comma-shaped bacillus of KOCH is neither universally present in choleraic excreta, nor to be found in any quantity in the intestinal wall; that it occurs in other intestinal affections; and that in its mode of development in artificial cultures it does not behave differently from the ordinary mode of growth of putrefactive bacteria. It is clear then, that they deny to this special form of bacillus any distinctive or pathogenic property, and that in almost every point their observations stand in direct contradiction to the very positive affirmations of the eminent Berlin authority.

In a matter of this kind, where there is such a conflict of testimony between experts, there is no means of arriving at a judicial decision, and we must be content to stand by whilst these scientists advance their arguments on the one side or the other. It is easy, of course, to assume that Dr. KOCH went out to Egypt and India with a preconceived idea of discovering a germ, and that he has allowed his usual scientific caution to be overridden by other considerations. It is just as easy to affirm that our Commissioners were equally bent upon disproving KOCH'S assertions, and suffered themselves to be blinded by this desire. But we may set aside such conceptions as unworthy to be held by scientific men, who are intent only upon the discovery of truth. Nor can we think that the instructions given to our Commissioners were limited by any such narrow notions, although we observe in the copy of correspondence between the Secretary to the Government of India, Home Department, and the Chief Secretary of the Government of Madras, issued to the House of Commons last July, that Dr. FURNELL, the Sanitary Commissioner of Madras, was taken to task for venturing to advance facts pointing to the apparent spread of an epidemic by contagion. The papers contain Dr. FURNELL'S reply to these strictures; but the fact that they were made seems to afford some clue to the reason why the Government so tardily decided to send out a scientific commission of inquiry. Whatever may have been the motives, or of what nature the instructions, we may well feel some disappointment that so little of a positive character has issued from the Commissioners' labours. At the same time, there is at least this ground for congratulation, that the Government recognise the question of the etiology of cholera to be one which, if capable of solution at all, is to be dealt with by medical science; and if the first fruits of this new departure are somewhat barren, we may cherish the hope that the work thus commenced will be prosecuted again and again, until conclusions as definite as those we possess regarding some

other zymotic diseases are obtained respecting this great scourge, that has its home and source in our Indian empire.

DR. ROBERTS BARTHOLOW of Philadelphia has just published a clinical lecture on the Physiological Action and Therapeutic Uses of the Permanganates, which will undoubtedly enhance his already high reputation as a careful observer and practical physician. It is often objected that permanganate of potash is so quickly decomposed on coming in contact with organic matter that its action must be feeble and transitory. There is reason, however, to believe that this objection cannot be maintained, and that in reality a very definite influence is exerted on the blood. When injected locally for the bite of a venomous serpent the poison is destroyed, notwithstanding the fact that it is in contact with organic material. The effect on the animal poison is purely chemical; it is antidotal but not physiologically antagonistic, so that to be effective it must be brought in actual contact with the virus, which it destroys by a process of oxidation. Given internally in small doses, say two or three grains well diluted, it exerts no irritating effect on the mucous membrane of the stomach, but if administered in large doses or in a concentrated form, it produces local heat, a sense of irritation, and even burning pain. It has been alleged that it cannot act beyond the stomach because its oxygen must there be appropriated by the organic matter contained in that viscus; but there is good evidence, both clinical and physiological, that it does produce a marked systemic effect. The investigations of VULPIAN, DEMARQUAY, HAYEM, WALDENBURGH, and others have thrown much light on the subject, and the researches of BINZ have been instrumental in clearing up much of the mystery surrounding the physiological action of ozone. The last-named observer finds that ozone has a hypnotic action, a calmative effect on the central nervous system, due in all probability to an impression on the grey matter whereby its functional activity is suspended. The powers possessed by permanganate of potash as a general stimulant are well shown in the active emmenagogue properties which it has been found to exhibit by RINGER and MURRELL. In amenorrhœa due to deficient activity it promotes the functions in a very remarkable degree. The class of cases to which the permanganate is adapted are those characterised by torpor, anæmia, or deficient activity of the menstrual apparatus. It is contraindicated whenever an acute congestion or a general condition of sthenic reaction exists. Confirmatory evidence on this point has been received in abundance from all parts of the world, and it is obvious that a power which can so stimulate the sexual apparatus must, when exerted in other directions, prove equally effective. Dr. A. V. VARGUININ essayed its administration in dysmenorrhœa characterised by scanty menstruation and anæmia. Much of course must depend on the mode of administration, and Dr. BARTHOLOW finds as the result of a large practical experience that it is best given in the form of compressed tablets, prepared without any excipient. These tablets are typically adapted to the purpose, and present advantages not possessed by any other mode of administration. A small dose repeated at short intervals, a grain or two every half hour, until from four to six grains have been taken, is preferable to the exhibition of this quantity at one dose, as the diffusion of the salt into the blood is more effectually secured. From its irritating effect it is contraindicated in cases of acute inflammation of the stomach, but it will be found of the greatest possible value in chronic gastric and gastro-intestinal catarrh, accompanied by fermentative changes in the food. Eructations of gas, vomiting of a yeast-like material containing sarcinæ, and an acid fermentation of the starchy and saccharine constituents of the food, are promptly relieved by the administration of the salt. When the catarrhal process extends to the duodenum and involves the bile-ducts, the remedy is equally efficient. In addition to the evidence of stomachal and intestinal indigestion there is present more or less biliousness, manifested by a muddy complexion, yellow conjunctiva, high-coloured urine, and general malaise. This is a common condition, resulting from the combination of several factors, chief and foremost amongst which are improper feeding and imperfect preparation of food for absorption. The permanganate does good in many ways: it checks fermentation of the food elements prone to this process, acts beneficially on the catarrh of the mucous membrane, and, above all, promotes oxidation in the tissues undergoing metamorphosis. The uric acid in the urine is converted into urea, in which form it is excreted. From these conclusions it follows that permanganate of potash must be a remedy of great value in lithæmia, and clinical experience is quite in harmony with these physiological deductions. It is also useful in an affection cognate to lithæmia—the hepatic form of glycosuria. The special field of its usefulness in relation to diabetes is in those cases in which there appear to be both over-production of glycogen and insufficient consumption of this material. It will be found of the greatest possible value in the obese subjects of glycosuria, in whom the presence of much uric acid in the blood signifies at the same time inadequate preparation for absorption of certain food constituents, and a supply of oxygen insufficient to convert uric acid into urea. For the same reason that the permanganates are useful in lithæmia and glycosuria, they constitute a valuable remedy for obesity. According to the experience of Dr. BARTHOLOW, there is no remedy more effective in the treatment of obesity, and for the relief of the disorders of digestion which have a pathogenic relation to this condition.

THE constant occurrence of cases appealing strongly to the sympathies of the profession is a very noticeable fact. Medical life in its ideal is like that of "virtuous HEBERDEN," divided into three periods, one of arduous learning, followed by one of equally arduous practice, at once beneficent and profitable, and this crowned by an age of honour, and authority, and rest—the rest only made sweeter by being used for formulating and transmitting the lessons of experience. There is nothing in such a life as his, extending over ninety years, to excite pain or regret. The very change from practice to rest is made easily: the summer spent chiefly at Windsor, and the favourite art, not to say the friendly patients, being still a chief concern of the winter months. This is the ideal, we say, of medical life—one to be worked up to by every medical student and every medical practitioner, but admittedly only an ideal, unattainable by the majority of the four-and-twenty thousand who compose the Medical Register. The ninety

years that were given to HEBERDEN for working out his life were in themselves a great and fundamental gift that is not given to many, and without which he could not have completed the picture and the model which are suggested by his character and his history. But still we must have the ideal, and demand of all good men and true that they work up to it. We may not reach HEBERDEN'S fame any more than we may reach his age, but we shall certainly get some way towards both by considering how he deported himself. There is one feature in his life that strikes us, and which is neither hopelessly inimitable nor completely irrelevant to our present purpose. He did not make haste. He was deliberate. He did not clutch at the sweets of life. And though he waited—shall we say because he waited?—all things came to him. He took all the great steps of his life deliberately, and he put his foot down firmly. Though he was born in 1710, he was not married till 1760. He practised ten years in Cambridge before he came to London, where he did not begin practice till he was thirty-eight. This was in the year 1748. His success soon became great, and some twelve years after coming to London, GEORGE III. wished him to become physician to Her Majesty the Queen. The proposal was significant, but more significant still was HEBERDEN'S respectful refusal of it. Such was the respect of the King for HEBERDEN that he not only took kindly his refusal of this great offer, but as kindly accepted HEBERDEN'S nomination of a friend for the office, Dr. LEATHERLAND, a man of great worth, learning, and modesty. Surely in this quality of deliberation, not to say slowness, we see some secret of HEBERDEN'S success, of his independence, of the dignity, and we must add the charity, of his life. We live fast now. We live in the time of a race of luxury. We must marry soon, and soon be rich. The motto of an old philosopher, "Quantis non egeo," is accepted with the omission of the little monosyllabic word in the middle, and before we are well diplomatised, we are saying, "How many things there are which I want and must immediately have." A large house, a showy carriage, and everything to match. Every want recognised is the parent of many more. In every branch of the profession, as indeed in every class of society, there is the same tendency to multiply wants and to complicate one's establishment. It is all well that ends well. But our pages tell only too pathetically that it does not always end well; on the contrary, that it ends painfully and pitifully. We are not demanding any unreasonable amount of prudence or self-denial in the forecast of life and success. We are not prescribing a gloomy celibacy for every man till he is fifty, or till he is assured of fortune and of fame. We are only reminding our readers that a little more slowness and deliberation in the great steps of life and a little more determination to keep wants few will bring their reward. They may not bring fame; but with reasonable diligence and forethought they will bring ease and competence, and secure those who look to us and may survive us from painful dependence on others. In London especially there is little excuse for any medical man leaving his family entirely unprovided for. There is a Society—that for the Relief of Widows and Orphans of Medical Men within the postal district of London—to which it is almost culpable for such medical men not to belong. Should they die poor, their widows and children are provided against destitution on easy and yet independent terms. Should they die in easier circumstances, they have the satisfaction of knowing that they have contributed to the help and comfort of less successful brethren. This Society has constantly to press its advantages on the profession, nevertheless, numbers of medical men die without the comfort of knowing that by subscribing to it they have secured these advantages for those whom they love. We are well aware of other circumstances in social and professional life at the present which make deliberation and providence difficult, but they do not make them less binding or the omission of them more excusable.

MR. THORNHILL HARRISON'S proposal as to an improved water-supply for the metropolis deserves serious consideration, the more so as it is the outcome of the experience which he acquired as one of the Commissioners appointed to inquire into the pollution of rivers in 1865, and of much thought since that date. His contention is that a vast body of wholesome water is in motion down the Thames valley, in addition to that which flows in the Thames river; and that, if the locality be properly selected, this water can be tapped and utilised at a comparatively small cost. The gathering-ground, resort to which he advocates, is that part of the chalk formation within the watershed of the Thames which lies to the north and west of Windsor, including the areas within the basins of the rivers Kennet and Colne, and which covers some 1100 square miles. Here the saturated chalk contains one-third of its bulk of water, and forms a huge reservoir of water, from which the supply passes away but slowly, except through fissures. Subject to such modifications as might be shown to be necessary after borings had been sunk, and the position of fissures determined, the constructive part of the scheme would involve a large receiving-well at Black Pots, with an overflow into the Thames below Windsor Lock, and a tunnel passing from this well in a westward direction; the tunnel to be a mile in length, and of gradually diminishing diameter. Incidentally it is mentioned that if London were thus supplied with water, the companies would save the heavy cost of filtering, the lands now occupied by their reservoirs and filtering-beds could be disposed of, and the £10,000 a year which Parliament requires them to pay to the Thames Conservancy Board for the purposes of diminishing the pollution of the water abstracted by them would be saved.

The proposal in question is included in two reports, which Mr. HARRISON has submitted to the President of the Local Government Board, and which have since been issued as a Parliamentary paper. The general scheme having been adverted to, the sources of supply are pointed out in detail; and then follows a description of the geological peculiarities of the gathering-ground and of the district from which the water is to be collected, and also details as to how the supply is to be delivered to the several companies now providing water for the metropolis. The reports are well illustrated, both geologically and otherwise, several of the maps being interesting, quite apart from the special subject under consideration. Thus, those explanatory of the description given as to the chalk ranges go much beyond the question of London water-supply, and point to the con-

clusion that the crushing of the chalk strata forming the great escarpments of which the remains are seen in the North and South Downs were contemporaneous with the elevation of the Alpine and Pyrenean ranges, with which they are respectively all but parallel. Two other maps indicate the course and sections of the proposed tunnel. The scheme in no way professes to be matured as regards its final details, but there seems no doubt that a vast quantity of pure water, ample for the supply of the metropolis, and in excess of what is required to maintain the needed flow in the Thames itself, is running to waste under our feet, and only waits to be collected. If it be true that financial difficulties need not stand in the way, a reasonable solution of an increasingly troublesome problem would appear to be at hand.

Annotations.

"Ne quid nimis."

LUNACY LAW REFORM.

WE are in no way anxious to rush impetuously into the midst of the controversial lists where the question of Lunacy Law Reform is again being vexed with the zeal of enthusiastic disputants. We prefer to stand by awhile, and wait until, haply, it shall become a certainty that the subject will actually engage the attention of the Legislature, and with a reasonable promise of serious business in result. Nothing need be added to, or taken from, the scheme of reconstruction which we have again and again propounded. We speak of reconstruction because this is a matter in respect to which the law needs to be subjected to radical reform, and it would be simpler, and better every way, to make a clean sweep of existing statutes and pass a short specific Act, than to endeavour to mend the statute book by piecing and annotating.

We agree with those who contend that the main requirements are specifically: increased protection for the sane, better and greater facilities for the prompt treatment of mental disease, and such relief of professional responsibility as may be consistent with the enforcement of salutary precautions against the wrongful confinement of those who are only eccentric without being dangerously mad. It has been disputed that any such distinction as that to which public prudence points between the simply crazy and the seriously insane is, or ought to be, contemplated. Some there are who would have everyone who entertains a belief contrary to their own placed under restraint lest "madness" may chance to spread. This desire is not an unkind wish; it is the natural outcome of a conviction which prevails among specialists that any mind which is a little disordered must needs be so because the brain behind it is diseased. If scientists who argue thus could only be induced to recognise the great Darwinian law, or principle of nature, that function is more than, and a development *precedes*, organism, they would understand that disorder—or "derangement" as it used to be called—is quite possible without disease. As a matter of fact, a very large amount, or degree, of disorder in mental function is not only innocuous, but curable. And, for ourselves, we must profess utter inability to divine why a man or woman who professes a belief in some strange doctrine—for example, that of metempsychosis—should be regarded as a lunatic on this ground alone, while the doctrine of "incarnation" *per se* is regarded as perfectly reasonable, and those are counted sane who believe in it. This is a strong example, but it is a simple recital of the ground on which certificates of insanity are sometimes given, and it is absolutely necessary to face the facts.

We hold, and must contend, that only one of two reasons can morally justify the putting away of a mentally disordered person into confinement, and one of these *moral* grounds of justification is not, we regret to say, a legal one. Only when it is necessary for the treatment or cure of the patient should recourse be had to personal sequestration; and only when he or she is so demented as to need protection from harm-doing, is it, in our judgment, right to place an innocent and suffering fellow creature in confinement. What public safety and the welfare of the community demand is perfect freedom to take such measures as are necessary for the treatment of mental disease. The common-sense view of the case is simply this: *If asylums were properly inspected, and were not private prisons, there would be no need for the present system of certifying*, which causes so much trouble, pain, and difficulty, which in itself is a fruitful source of brain irritation, and which inflicts a life-long injury by impressing its victims with an indelible brand. Private prisons—miscalled asylums—ought not to be allowed to exist, and then there could be no question of neglect or malfeasance in the signing of *lettres de cachet*.

This is the one remedy for all the abuses of lunacy law and practice of which some justly, and many unjustly, complain. We are not inclined to discuss projects of law which are more than in the clouds. When the Government Bill—if such a measure be really forthcoming—is printed, we will review its provisions; but only such a measure as would at once put an end to the private asylum system and existing method of certification would, in our judgment, be satisfactory, or meet the ends of the case as it stands.

ADULTERATION OF FOOD AND DRUGS.

THE official account annually issued as to the working of the Sale of Food and Drugs Act, 1875, is always interesting. From the report for 1883 we learn that the actual number of analyses carried out under its provisions is on the increase, but that the public rarely set in motion the necessary machinery for the suppression of adulteration. Of 19,648 articles examined 2955 were found to be adulterated, and the percentage of adulteration in the following articles was considerable. In spirits it was 22·5 per cent., in milk 20·0, in coffee 19·1, in butter 18·0, and in drugs 16·4. Under Dr. Hassall's examinations made for THE LANCET Commission in 1854-56 more than half the articles were reported against; in 1877 the proportion was 19·2, now it is 15. Hence, some progress is being made, and fortunately the character of the adulterations practised is much less harmful than formerly. The question of milk adulteration by the addition of water still remains serious. One-fifth of all the samples subjected to analysis were found thus adulterated, and so long as it is possible for milk vendors to procure from the public between £70,000 and £80,000 a year for water sold under the name of milk, and this without adequate punishment when detected, so long is the practice certain to continue. Thus, it is stated in the Report that the public analyst for Plumstead calculates that in that single district the milkmen receive between £7000 and £8000 for water, while the fines for adulteration imposed on them collectively amount to about £100 annually. The extensive sale of drugs, which prove on analysis to be not in accordance with the Pharmacopœia, is another matter of serious importance. In some cases expensive drugs are so diluted that the quantity prescribed is not present, but in still more numerous instances drugs which were originally badly prepared, or which have deteriorated by keeping, are sold, and hence they are certain to fail in producing the effects intended by the prescriber. An increasing amount of publicity is now being given to

this subject of adulteration, and it is to be hoped that private purchasers will co-operate with the authorities in putting it down by themselves procuring samples when they suspect that drugs have been tampered with.

DEATH FROM SEPTICÆMIA AND HÆMORRHAGE.

DR. DANFORD THOMAS held an inquest at the Crowndale Hall, Crowndale-road, St. Pancras, on Saturday, Jan. 3rd, touching the death of Eliza Simpson, a middle-aged woman. The deceased had been under treatment for necrosis of the upper jaw and gangrenous stomatitis, and Mr. Brown, her medical attendant, on the expectation of letting out some pus, made an incision into the cheek from without, and ordered a poultice to be applied. Unfortunately the bleeding continued until the patient's death from exhaustion, which took place in about half an hour. Seeing the alarming condition of his wife, the husband sent for Mr. Brown, but that gentleman was from home. Accordingly Mr. Whitefoord was called in, but he arrived too late to be of any service. The quantity of blood lost was estimated at from half a pint to a pint. At the post-mortem examination, made by Mr. Pepper, it was observed that the greater part of the left upper jaw was denuded of periosteum, and the cheek on the same side was in a state of gangrene. The incision, two-thirds of an inch long and one-third of an inch deep, had not wounded any large vessel. The following signs of septicæmia were well marked. Petechial extravasations on the skin and on the under surface of the dura mater, enlargement and softening of the abdominal viscera, and marked fatty degeneration of the heart. It may be noted that the gall-bladder was enlarged and distended with clear fluid, partly serous, partly mucous. It contained several calculi, one of considerable size being impacted in the cystic duct. Mr. Pepper gave it as his opinion that the continuous hæmorrhage was due to deficient coagulating power of the blood, and to inability to contract on the part of the severed vessels, owing to molecular disintegration of their walls, and their fixation by inflammatory lymph; and, further, that whereas the loss of blood was not in itself sufficient to cause death, it did so under the circumstances narrated above. The jury returned a verdict in accordance with the medical evidence. There can be no doubt that Mr. Brown did not apprehend such an untoward event, or he would not have left the patient until the bleeding had ceased. The case is a very instructive one, showing the danger attending incision of tissues (naturally very vascular) in a state of extreme congestion.

CURING UNSOUND FISH.

IF the general purchaser is to be protected against the risk of disease from eating fish which is putrid or not quite fresh, and the detection of its unfitness when in the shop depends chiefly on his own intelligence, there is all the more need that inspection in the market should be deep and searching. We speak advisedly, as a recent case of faulty packing at Billingsgate shows. A retail dealer found that out of a quantity of fish purchased by him, and immediately afterwards inspected, those in the top layer were sound, the others more or less putrid. The defence urged against his complaint was as novel as erroneous. It was stated that the fish were sold as being of mixed quality, but saleable on the ground that those which were unsound, and thus rendered uneatable, might be cured and sold in the dry state. Salting and smoking are, no doubt, good means of preserving fish by preventing putrefactive changes. Their action, however, is somewhat uncertain; it cannot be expected to penetrate with equal intensity through every tissue, some being more exposed to it than others. Neither can putrefaction once established be arrested in this way. At the very outset of the change, while it is yet slight or superficial, curing may, it is true, suffice to eradicate it; but at such a stage the taint of decay is barely perceptible. It would be altogether unjustifiable to found any general rule which would ascribe to the curing process a more than merely preventive influence in this respect. Brine itself, on the other hand, is too apt to become impregnated with mucus and other animal matters from the fish immersed in it. If to these bacteria be added, we have in the preservative medium all that is required for promoting active decomposition. Drying fish by smoking them at a moderate temperature, though a practice based on another principle from that of salting, supplies no further guarantee against organic change. This latter is something which we cannot rely upon nipping in the bud, and for which, therefore, as we have shown, "curing" is no cure.

LONGEVITY IN THE SOCIETY OF FRIENDS.

A LETTER published in a recent issue of the *Alliance News* affords an example of the misuse of one-sided facts, which, in connexion with an interesting subject, is itself not devoid of interest. The exceptional longevity in the Society of Friends is stated to be a fact acknowledged by actuaries, and the newly issued figures for the year 1883-84 are said to present the increasing longevity in a "startling aspect." It appears that certain vital statistics have been recorded, tabulated and published by the Society of Friends for a series of forty-one years, and it is pointed out that while the mean age of 342 persons dying in 1843-44 was fifty years and nine months, the mean age of 280 persons dying in 1883-84 was sixty years and eleven months. The mean age of those dying in the six years 1843-44 to 1848-49 was fifty years and four months; in the six years 1872-73 to 1877-78 it was fifty-five years and five months; and in the six years 1878-79 to 1883-84 it was fifty-eight years nine months. It may safely be asserted that there are few methods of calculating longevity more open to fallacious results than the use of the mean age at death for this purpose. In a theoretical life-table population the mean age at death is synonymous with the mean duration of life, but without accurate knowledge of the age constitution of a population, the mean age of its decedents is absolutely valueless as a test of its longevity. Mr. Pearson, in the letter to which we refer, admits that even the number of members of the Society in 1843-44 is not recorded, but adds "the number is no doubt practically about the same for both periods"—that is, for 1843-44 and 1883-84. But the number of members, even if it were known, for each year in the series, would have little value unless the ages of the members were also known. If from any cause the Society of Friends now contains a larger proportion of elderly persons than it did forty years ago, then the comparison of the mean age at death at the two periods would be about as useful as a test of health and longevity as a similar comparison of the mean age at death of captains and colonels in the army which was suggested by the late Dr. Farr, more than forty years ago, as the *reductio ad absurdum* of this false method of mortality statistics. The number of this sect is estimated at "some 18,000 persons of all ranks and conditions of life," but further figures quoted by Mr. Pearson point strongly to the probability that the number of the Society has declined, and that the proportion of young people among the members has also declined. Until light has been thrown upon the age constitution of the Society, all conclusions drawn from the mean age at death must be regarded with suspicion. It would, at any rate, be well to establish the fact of this "startling" increase of longevity among the Society before accepting the final conclusion of Mr. Pearson that "this religious

Society, always 'temperate' in the use of alcholic liquors, have practically become a Society of total abstainers, and the statistics of longevity I have just presented show most conclusively how they are already reaping their reward." This is indeed a case of the zeal of temperance advocates outrunning their discretion.

PUBLIC HEALTH LEGISLATION OF 1884.

AMONGST the Acts of Parliament which received the Royal assent during 1884 the following affect sanitary authorities in their dealings with public health. The Canal Boats Act, 1884, amends the Act of 1877 in several important respects. Every sanitary authority within whose district there is a canal will now be compelled to enforce the regulations of the Act and to make a report during the month of January as to what has been done during the preceding year. For the purposes of administration alterations have been made as regards the imposition and disposal of fines; certificates of registration heretofore granted now become null and void if any structural alterations are made affecting the conditions under which the registration was originally made; power of entry for the purposes of inspection is sanctioned from six in the morning until nine at night; and boats registered under the Merchant Shipping Acts, which thus evade the Canal Boats Act, may, under certain specified conditions, be brought within the control of the latter. The Public Health (Confirmation of Bye-laws) Act, 1884, will remove a doubt which a recent decision created as to the adequacy in certain cases of confirmation of bye-laws by the Local Government Board. The Disused Burial-Grounds Act, 1884, makes it unlawful to erect buildings on any disused burial-ground, except as regards extensions of places for public worship and buildings for which a faculty was obtained before the closing of the principal session of 1884. The definition "disused burial-ground" includes a burial-ground in respect of which an Order in Council has been made for the discontinuance of burials therein. Under the Expiring Laws Continuance Act, the Diseases Prevention (Metropolis) Act, 1883, which removes the stigma of pauperism from persons received into the metropolitan asylums board hospitals, was renewed for another year.

DAIRIES AND SEWAGE FARM PRODUCTS.

SOME difficult questions have arisen in connexion with the proposal of the Croydon Corporation to let some of the land they possess at their sewage farm for the erection of cowsheds to hold between two and three hundred cows; the animals to be to a considerable extent fed on the rye grass grown on the farm. The objections to the scheme were mainly raised by residents at Hackbridge, who maintained that the cowsheds would cause a nuisance; that so large an aggregation of cows was objectionable, amongst other reasons because it would facilitate the spread of foot-and-mouth disease; that the keeping of the cows on rye grass would be likely to injuriously affect the milk; and that the cows, by using the effluent water of the farm as a beverage, would secrete a milk calculated to bring about disease amongst the consumers. So far as we are aware no positive evidence has yet been adduced as to injury either to man or beast from proximity to, or consumption of articles grown on, sewage farms; and as regards this special farm, Dr. Alfred Carpenter read an exhaustive paper before the International Medical Congress in London, showing that no such injurious results as had been anticipated had ever been brought about. The Local Government inquiry which has been held as to the use of the land in question for the purposes of cowsheds, has, however, left one point in a very unsatisfactory state. Although it may be contended that the consumption by cows of the effluent from a sewage farm has never yet been shown to give objectionable qualities to their milk, yet it must be held that it is wrong as regards milch cows supplying milk for human use, to allow any such water to be resorted to. The evidence given at the inquiry, and the correspondence which has ensued, go to show that the cows have on certain occasions been allowed to drink the effluent, and if the transfer of the land be sanctioned it is to be hoped that it will be made conditional on a supply of wholesome water being so conveyed to all parts of the premises that there shall be no possible inducement to resort to the effluent for any purposes connected with these dairy sheds.

PATHOLOGICAL SOCIETY.

THE formal annual meeting of the Pathological Society took place in the course of the meeting held on Tuesday evening last. The scrutineers, Dr. J. A. Ormerod and Mr. Arbuthnot Lane, declared that the list of officers nominated by the Council had been duly and unanimously elected. We published this list in THE LANCET of December 27th, 1884. Mr. Butlin, Hon. Sec., then read the report of the Council, which showed that the Society was in a flourishing state, and numbered now 684 members. Reference was made to the loss the Society had sustained in the decease of Dr. Mahomed, and of Mr. Wheatley, the resident librarian. After many years of valuable work Mr. Marcus Beck and Mr. Godlee have retired from the Morbid Growths Committee, and Dr. Sharkey and Mr. Eve have been elected to fill their places. Mr. Bland Sutton has been elected to take charge of the section of comparative pathology. Mr. Waren Tay proposed, and Dr. Angel Money seconded, that the report of the Council and the balance-sheet of the Treasurer be received, adopted, and printed in the Society's Transactions. This proposition was duly carried. Dr. Hale White and Mr. Bowlby were appointed to audit the Treasurer's balance-sheet. Mr. John Wood proposed, and Dr. Norman Moore seconded, a vote of thanks to Mr. Hulke, the retiring President. This was carried with acclamation, and Mr. Hulke briefly replied by saying that were it not for the able assistance of the Hon. Secretaries the work of the Society would be almost at a standstill. Dr. Longhurst proposed, and Mr. W. Haward seconded, a vote of thanks to the retiring Vice-presidents and Members of the Council.

ARTIFICIAL ANUS CURED BY ENTEROTOMY.

DR. CANNIZZARO, in the *Rivista Internazionale di Medicina e Chirurgia* for last month, reports the case of S. P——, aged sixty-seven, who for some years had had a reducible right inguinal hernia. Symptoms of strangulation supervened, and a surgeon, after ineffectually applying the taxis, advised operation. The patient objecting, the hernial coverings sloughed, and an artificial anus was established in the right groin. When Dr. Cannizzaro operated on the 1st of last October he found the septum or spur (*lo sperone*) very well marked. Having grasped it in its whole depth within the blades of the enterotome, he tightened the screw until the patient complained of pain in the part and at the epigastrium. The instrument was immobilised with a spica bandage and compress. During the first day the patient was much depressed, and inclined to vomit. The dressing, changed each day, contained fæcal matter; each day also the screw was tightened until the patient complained of pain. Chicken broth, eggs, and wine were taken freely. During the fifth night the bowels acted abundantly twice and naturally. On the sixth and seventh days very little fæcal matter was found around the dressing, and on the eighth day the enterotome was observed to be very movable. It could not then be detached, but it came away with the dressing on the ninth day after

operation. The wound was then washed with carbolised water, its surroundings brushed with collodion, and a compressing bandage applied. From this date the patient continued to evacuate per anum; in reapplying the bandage daily, care was taken to approximate the edges of the wound, which gradually healed; the patient leaving the hospital cured, in excellent health, on the 15th of November, just forty-five days after the operation.

SLEEPLESSNESS.

SLEEP is a perfectly natural function. It is not a negative act, but a positive process. Herein lies the difference between real sleep and the poison-induced torpor which mimics the state of physiological rest. We ought to be able to sleep at will. Napoleon and many busy men—the late Mr. Wakley, for example—developed the power of self-induced sleep to such an extent as to be able to rest whenever and wherever they pleased, for longer or shorter periods, as the conditions admitted. We have been led to believe that Mr. Gladstone at one time possessed this faculty. If that be so, his recent insomnia must be assumed to have been the result of such intense brain-worry as inhibited the control of the will; or there may, of course, be physical causes which render the apparatus of the cerebral blood-supply less manageable by the nerve centres. In any case, it is much to be deplored that, in the study and treatment of insomnia, the profession generally does not more clearly and constantly keep in memory that what we call sleeplessness is really wakefulness, and that before it is justifiable to resort to the use of stupefying drugs the precise cause of disturbance should be clearly made out. This, of course, takes time, and involves a scientific testing of the relative excitabilities of the sense-organs, central or radial and peripheral. The discovery of the cause, however, affords ample recompense for the trouble of searching for it. With the sphygmograph and a few test appliances, such as Galton's whistle, an optometer, and other instruments, the recognition of the form and cause of sleeplessness can be made in a brief space, and then, and then *only* we protest, it can be scientifically—i.e., physiologically—treated.

THE LEGACIES OF 1884.

THE legacies and donations of 1884, in the provinces as well as in the metropolis, have been numerous and generous. We rejoice over them as proofs that the old Christian virtue—and Jewish, too, for that matter, the largest being that of the Baroness de Rothschild, who, of £99,000, left £10,000 to the London Hospital—of charity is not dead yet, in spite of all the pains that have been taken of late years to take the life and the grace out of it. Mrs. Johnstone Thomson, of Claremont, Lockerbie, left £25,000 for almshouses. Mr. John Harrison, of Bath, £29,000 for the blind. Mr. Moffatt, of Port Glasgow, £60,000 for an orphanage in Renfrewshire. Sir Erasmus Wilson left £5000 each to the Margate Infirmary, the Society for Widows and Orphans of Medical Men, the Royal Medical Benevolent College, and the Medical Benevolent Fund. Mrs. Charles Turner, of Liverpool, has given £30,000 for a Home for Chronic Sufferers, a class most to be pitied, and a sum the interest of which will meet the annual expenditure. These acts of generosity revive one's spirits and one's faith in human brotherhood. They show that the accumulation of wealth does not obliterate thoughts of the poor, and the maimed, and the halt, and the blind. We would fain see them greatly multiplied, and the hospitals and asylums embarrassed with wealth, as they now are embarrassed by the want of it. Why not? What good is there in keeping money, even during life, in huge masses, when it is so urgently wanted, and could be so immensely useful? This spontaneous return of money to the poor by the rich is the blessed way and the best of solving all angry questions about the unequal distribution of wealth. We again express our belief that there is no better medium for distributing gifts to hospitals, whether in the shape of donations or legacies, than the Hospital Sunday Fund.

RHIGOLENE: A LOCAL ANÆSTHETIC.

THE use of cocaine as a local anæsthetic has directed attention to the value of petroleum naphtha for similar purposes. The name rhigolene was given by Dr. H. J. Bigelow, of Boston, to a light inflammable liquid obtained by the repeated distillation of petroleum. It is probable that it is not a definite chemical compound, but it is said to be one of the most volatile bodies in existence. By using it in the form of a spray with a common atomiser it produces a degree of cold sufficient to freeze any tissue with which it may come in contact. Dr. W. Chapman Jarvis, of New York, finds that its action is more decided than that of cocaine, although of shorter duration. Skin and mucous membranes may be divided deeply and freely without fear of pain or hæmorrhage. Its effects pass off quickly, so that the operator has to act with promptness. It is a good plan to employ it in conjunction with cocaine. When not in use it should be kept on ice or in a cool room, tightly corked. In a warm place it would probably burst the bottle or blow out the cork. It has been accused of possessing explosive properties, but probably it is safe if not brought in contact with an open flame. It should not be used for cases which require artificial light. Very little is known about it as yet, although its properties were cursorily investigated some years ago.

THE SANITARY STATE OF ALNWICK.

THE town of Alnwick, in Northumberland, has recently acquired an unenviable notoriety for dirt and disgraceful house accommodation for the lower classes, and it has, in consequence of the revelations made at a coroner's inquest, been visited by an inspector of the Local Government Board. The recent discussions in the Town Council are not hopeful as regards the future, for the Corporation, having only just determined that the piggery nuisance must be abated, and having procured the sanction of the Local Government Board to a clause specifying a distance from dwellings within which pigs shall not be kept, have now practically decided not to enforce the bye-law universally, but only as the occasion may seem to suit. It is this discretionary power in certain bye-laws which tends to do so much harm, the more so as it always leaves the door open to allegations of favouritism or the reverse. The official report, when issued, may give some further insight into these matters.

CHOLERA IN RAGS.

THE orders relating to the prohibition to import rags into this country from France and Italy having expired at the close of last year, it was anticipated that the trade would have been resumed, but fresh orders have been issued, signed by Lord Kimberley, one of the *ex-officio* members of the Local Government Board, extending the prohibition until the first day of March next. The fact that occasional cases of cholera have been reported both from France and Italy since the outbreaks were regarded as having ceased makes it difficult to say that the danger of a recrudescence has passed away, and it is not improbable that rags from infected areas may be prevented from coming into this country, except subject to the conditions of the prohibitive orders, until it seems tolerably certain that the disease has really finally subsided.

PREVENTIVE MEDICINE IN PRIMARY SCHOOLS.

THE suggestion of supplying a good meal to the poorer children who attend Board Schools is not new. On the other side of the Channel, at least, it has been carried successfully into effect. In the admirably administered capital of Belgium all the children attending the communal schools are examined by the doctors attached to the sanitary service of the town. Those among them who manifest signs of debility are at once put under a preventive treatment, which consists generally of cod-liver oil in winter and a tonic mixture in summer. There is a rule directing that each child should have a separate medicine glass of its own, and that the medicine should be given by the masters at school. If the medicine were taken home it would never be administered with proper punctuality, and the oil might at times be used to grease the father's boots. Of some 10,000 children there were 1094 treated in this manner from 1882 to 1883 at Brussels. Of this number 69, or 6·3 per cent., were completely cured, and 628, or 57·4 per cent., were much benefited. In 203 cases, 18·4 per cent., no improvement was noticed, while the result is unknown in 194, or 17·7, of the cases. The removal of the children to other towns or other schools accounts for the incomplete character of the statistics, but sufficient has been said to show on what a large scale this system of preventive medicine has been applied. It is needless to add that the medicine and medical supervision are entirely gratuitous; but the State is already beginning to recoup its outlay, for every year shows a distinct improvement in the health and physique of the military recruits. The teeth of the children are also examined; and during the same year no less than 1250 pupils required the services of the dentists, which they would probably have never obtained but for this compulsory intervention of the State. It will be seen therefore that, if we are not to be behind the Belgians in our care for the physical welfare of the children attending our primary schools, there is something more to be done than merely providing penny dinners.

IMPROVED DIET AT LONDON HOSPITALS.

AMONGST other improvements which the new year has introduced is a new scale of diets at St. Thomas's Hospital. By the system of cooking which has been adopted under the advice of Mr. Buckmaster, the authorities are enabled to diminish the expense; and the diet table, which has been drawn up by the medical staff of the hospital, is both varied and liberal. The quantity of animal food allowed to the convalescents is increased, and they are given bread *ad libitum*. Special diets are a feature of the new table, and throughout there is a decided improvement. The step is worthy of the attention of the authorities of other hospitals.

FLYING AMBULANCES IN PARIS.

DR. HENRI NACHTEL, though an American, has succeeded in starting an agitation in Paris in favour of organising town ambulances on the American model. An influential temporary committee has been formed for this purpose, on which we find the names of Dr. Pasteur, Dr. Berthelot, Dr. Guérin, Dr. Béclard, Baron Larrey, Senator Kœchlin Schwartz, the former Prime Minister M. Jules Simon, and the well-known journalists MM. Lockroy, John Lemoinne, E. Magnier, &c. A recent meeting of this committee was held under the presidency of M. Jules Simon, when Dr. Nachtel exposed his scheme. He proposed to establish two methods of communicating with the hospitals in case of accidents. First, when there is no extreme urgency, the local police station would supply means of telegraphing to the nearest hospital to send an ambulance. Secondly, when there is not a moment to be lost, or the case is too serious to bear transportation to the police station, telegraphic posts, similar to the fire alarms placed in the streets, might be employed. A number of red boxes or pillars in all the principal streets could be opened by a key kept in the nearest shop and the alarm given. On the receipt of this signal an ambulance should be ready to start in forty-two seconds, horses being kept day and night in harness. The house-surgeon would accompany the ambulance. It was further proposed to raise a fund by voluntary subscriptions to start this service; and a magnificent fête will forthwith be organised, the proceeds to be devoted to this purpose.

THE LATE DR. MARSHALL.

A PARAGRAPH in the last issue of THE LANCET relating to the death of Dr. William Marshall, late Physician to the Queen, requires a little correction. Dr. Marshall was originally in practice at Balmoral, and was occasionally called in to attend some of the persons about the court; and upon one occasion, when the Princess Louise was suffering from synovitis at Balmoral in 1872, the Queen saw him, and was so much pleased with his treatment of the case that he was appointed Her Majesty's own private resident medical attendant, and this position he held till he retired three years ago in bad health, having symptoms of brain mischief. He then received a very liberal pension from the Queen, and was succeeded by Dr. James Reed, who continues to hold the same post at Court at the present time. Dr. William Marshall was one of Nature's noblemen, a clever doctor, the soul of honour; he filled a most difficult post, and acted on all occasions with rare tact and extraordinary discretion. He was much beloved and very highly esteemed by all who came in contact with him. He now and then prescribed for the late Duke of Albany, as he also did for all the other members of the Royal Family when they were visiting Her Majesty. But Mr. Royle was the only constant medical attendant of the late Duke since 1875 till the time of his death.

COCA AND COCAINE IN SKIN DISEASES.

IN a recent lecture delivered at the Philadelphia Hospital for Skin Diseases Dr. John V. Shoemaker stated that for over two years he had employed a liquid extract of coca in the treatment of certain cutaneous affections. It had been employed with good results in eczema, herpes, herpes zoster, urticaria, and a number of allied affections. A case of acute eczema of the ear and neck was exhibited which had improved in the most marvellous manner under the local application of an ounce of fluid extract diluted with three ounces of water. In acne rosacea the solid extract should be made into an ointment with lard and applied freely. It exerts a marked sedative action upon the inflamed or irritated skin, and may be employed with confidence. We understand that Dr. T. C. Fox is using at the Westminster Hospital a solution of hydrochlorate of cocaine in cacao butter, and has obtained good results, especially in urticaria and lichen planus.

THE PRELIMINARY SCIENTIFIC EXAMINATION.

AT the meeting of Convocation of the University of London on Tuesday last, Dr. Curnow moved, and Mr. M. P. Christie seconded, "That Convocation again urges upon the Senate the desirability of holding the Preliminary Scientific (M.B.) Examination twice a year." The resolution was carried by 116 votes to 2. After such an expression of opinion on the part of the graduates, and with a rival in the shape of a teaching university threatening to compete with it in giving degrees in medicine, we anticipate that the Senate will grant the demand of Convocation, and not repeat its foolish policy of 1880 and 1881.

THE HEALTH OF MR. GLADSTONE.

WE are glad to be able to give a satisfactory account of the health of Mr. Gladstone. The disorder of his health, consisting chiefly of slight catarrh and lumbago, with sleeplessness, is only too easily explained by the late prevalence of east winds, following the exhausting work of the summer holidays and the autumn session, and coinciding with an anxious and complicated state of public affairs. It is not the first time that such attacks, occurring in similar circumstances, have shown that even Mr. Gladstone's powers have their limits. Happily, his ailments have already promptly yielded to apt remedies and to comparative rest, and there is a fair prospect that, without public inconvenience, his health may be soon fully restored. According to our latest account his sleep has returned, and this means almost everything that can be wished. At the same time, it would be a mistake to make too light of these attacks, or to refuse to see that if Mr. Gladstone's powers are to be conserved for the fullest advantage of the State, his friends should contrive in every way to keep him from all but essential work.

THE RIGHT OF SEARCHING A DEAD BODY.

A DISPUTE is raging between the authorities of Charing-cross Hospital and the Deputy Coroner for Westminster as to the right of searching a dead body. Obviously this right alone properly belongs to the police. It is often of the utmost importance that the pockets of a person found dead, or supposed to be dead, should be *instantly* investigated. Take the case, for example, of a man who had swallowed a narcotic poison which was acting powerfully; something in his pocket, such as an empty bottle or a written confession, might lead to the adoption of means for his recovery. Or, in the case of a murder, the discovery that pockets had been rifled, or something found in them, might supply a clue to the criminal. We are strongly of opinion that not a moment should in any case be lost before making a thorough search, and, beyond question, the person to do so is neither a hospital porter, who has no further responsibility, nor the coroner's officer, who is pretty sure not to be on the spot but a police constable, and the nearest at hand.

AMYLASE.

AMYLASE has been found by M. Brase to be present in a very large number of leaves of plants: potato, maize, dahlia, beet, tobacco, castor oil, red poppy, and sunflower. The principle is obtained by digesting the bruised leaves in cold water for twenty-four hours; the juice is then expressed and one and a half times its volume of 90° alcohol is added and the liquid filtered. After filtration the same quantity of alcohol is added and the liquid set aside to deposit. The precipitate is filtered off and washed with a small quantity of 65 alcohol. The amylase when present is contained in the precipitate, and its presence is proved by its action in converting starch into sugar.

A LUNATIC IMPRISONED.

THE Lord Mayor did not show his accustomed sagacity on Monday last when he sent Herbert Percy Freund to prison instead of to an asylum. This poor man was, we are informed, a St. Thomas's Hospital student some seven or eight years ago, and while there became insane. He has since been in Bethlem Hospital and in the City Asylum at Stone, of course under certificate. To place such a person in prison would be an act of cruelty, only that, of course, the mistake made has been the result of ignorance, not ill-feeling. The Secretary of State for Home Affairs must now be moved to interpose, and the man, who is not legally a criminal, and who therefore has been sent to prison contrary to law, be removed to an asylum. Setting aside personal considerations, this is absolutely necessary on public grounds, for at the expiration of the term of imprisonment—namely, two calendar months—the lunatic will be again at large, and his fanatical mania may, for aught anyone can tell, take the form of a possession or impulse to, enforce his views of religious awakening in a way which may not be safe for himself or those around him.

SMALL-POX HOSPITALS.

A MEETING of the Society of Medical Officers of Health will be held at 1, Adam-street, Adelphi, on Friday, January 16th, at 8 P.M., when the question "Are Small-pox Hospitals necessarily a source of danger to the neighbourhood in which they are placed?" will be discussed. Papers will be read in the affirmative by Drs. Tripe and Gwynn, and in the negative by Dr. E. T. Wilson.

AT a meeting of the Faculty of Medicine of the Melbourne University, on Oct. 29th, a letter from twenty-two medical students was considered, and ultimately referred to the committee already appointed to revise the medical course. In the letter attention was drawn to the following points, in which the surgical education of those signing it seemed susceptible of improvement:—1. No regular clinical instruction, as lately provided for by the council, is given in the wards. 2. Little or no instruction is given in therapeutics. 3. Consultations as at present conducted are useless as a means of education. Most of the operations are performed at from 2 to 3 P.M., at which hour the students are present at lectures; attendance on an operation may cause the loss of a valuable demonstration. 4. In many cases the operator gives no information as to the nature of the injury or disease demanding operation. 5. Owing to the present method of recording attendances at the hospital, no credit for attendance is given unless students attend their own particular wards; consequently it is impossible to give due attention to the out-patients' department, where many instructive cases are to be seen.

ACCORDING to the *Publishers' Circular*, the analytical table of the book issues of 1884 shows an increase of 228 over those published in 1883, the numbers being 6373, against 6145. Of the total issues of new books theology stands at the head with 724 volumes; juvenile works and tales stand second with 603; educational, classical, and philological books, 543; history, biography, &c., 490; books on the arts and sciences and illustrated works, 432; novels, tales, and other fiction, 408; year-books and volumes of serials, 323; voyages, travels, and geographical works, 236; pamphlets, sermons, and miscellaneous works, 208; and then, with less than 200 volumes, come poetry and the drama, 179; law, jurisprudence, &c., 163; medicine, surgery, &c., 160, this last showing a decline of 3 as compared with 1883. The new editions of medical works published during 1884 amounted, however, to 55.

DR. THEODORE WILLIAMS will deliver three lectures at the Brompton Hospital on Wednesdays, January 14th, 21st, and 28th, at 4 P.M., on the Uses of the Compressed Air Bath in the Treatment of Disease. Members of the profession are admitted on presentation of their cards.

AN alarming outbreak of scarlet fever is reported from Kirby Stephen, Westmoreland, over two hundred children in a small population having been attacked, and many deaths having occurred. The Board and Sunday schools have been closed.

MR. W. H. POWER, Medical Inspector of the Local Government Board, has issued a circular to the medical practitioners in the neighbourhood of Chelsea, Fulham, Kensington, and Hammersmith, requesting them to give him henceforward, until January, 1886, notice on the book-forms with which they have been supplied of each small-pox case, the very mild as well as the more severe, coming under their observation in the districts in question. Mr. Power states that the response accorded by the medical profession to his request in July last for information respecting occurrences of small-pox has been of very great service in his inquiry as to the distribution of the disease in those districts. We trust that practitioners will afford Mr. Power willing aid.

AT the meeting of the Royal Medical and Chirurgical Society on Tuesday, January 13th, it is expected that the evening will be taken up with the adjourned discussion on Dr. Percy Kidd's paper on the "Distribution of the Tubercle Bacilli in the Lesions of Phthisis." The President, Dr. Herman Weber, Dr. Green, Dr. Wilson Fox, Sir Andrew Clark, Dr. Moxon, Mr. Watson Cheyne, Dr. Coupland, Dr. Goodhart, Dr. Heron, and others, will take part in the discussion. Dr. Kidd's specimens will be on view half an hour before the meeting.

DR. DENHAM, ex-President of the Royal College of Surgeons, Ireland, having intimated his intention to retire from the active practice of his profession, a committee has been appointed to arrange for the presentation to him of an address and suitable testimonial (the subscription to the latter being limited to two guineas), as a token of the high esteem and regard in which he is held by his professional brethren and the public at large. The honorary secretaries are Drs. G. H. Kidd and Lombe Atthill.

IT is asserted on good authority that Prof. Recklinghausen of Strasburg is to be invited to fill the chair of Pathological Anatomy rendered vacant by the death of Prof. Cohnheim. Next in order come the names of Prof. Ziegler and Prof. Birch-Hirschfeld; but the name of Dr. C. Weigert, for several years the colleague of Cohnheim, does not appear in the list submitted by the Leipsic Faculty. Some natural dissatisfaction has been aroused in consequence.

THE death is reported of Prof. William Darling, F.R.C.S., who occupied the chair of anatomy in the University of New York. Dr. Darling received his professional education in the University of Edinburgh and became a Member of the Royal College of Surgeons of England in 1856 and a Fellow of the same College ten years later. He was the author of Anatomography and Essentials of Anatomy, and edited Professor Draper's works.

AT a meeting on the Southend-on-Sea Local Board of Health, held on Tuesday last, it was unanimously resolved, "That this board will strenuously oppose any scheme for sewage disposal involving the treatment or discharge of sewage or sewage liquid from London and its neighbourhood in the Thames, whether at Hole Haven or elsewhere, near, or so as to be calculated to injure, Southend."

WE are glad to learn that the Admiralty have ordered an official inquiry into the alleged excessive frequency of floggings on board Her Majesty's ship *Northumberland*.

THE death is announced of Dr. Edward Jarvis, of Dorchester, Massachusetts, President of the American Statistical Society, at the age of eighty-two.

THE vacancy caused by the retirement of Dr. Russell, for many years physician to the Birmingham General Hospital, is, we understand, likely to be filled by the appointment of Dr. Robert Saundby, with whose contributions to the morbid anatomy of mental and nervous disease the profession is familiar. Dr. Saundby's candidature is, it is said, unopposed.

THE committee charged with the provision of a permanent memorial to Dr. Paget, Regius Professor of Physic in the University of Cambridge, has decided that such memorial shall take the form of a marble bust to be placed in Addenbrooke's Hospital. The subscription list has been headed by the Prince of Wales and Prince Edward.

IT is announced that the synthesis of saccharose has been accomplished by MM. Aubert and Giraud, and it is anticipated that the discovery may eventually be of vast importance to the sugar industry. The amylaceous matter of the potato is first converted into glucose and then exposed to the action of a strong electric current.

AT the next meeting of the Obstetrical Society (Jan. 14th) a paper will be read by Dr. William Duncan on "Total Extirpation of the Uterus for Cancer." It is expected that Sir S. Wells, Sir W. Mac Cormac, Mr. Bryant, Mr. Thornton, and others will take part in the discussion.

THE emigrant ship *Hereford*, from Calcutta for the West Indies, has put into Mauritius for medical advice and has been placed in quarantine, fever having broken out amongst the passengers and eighteen deaths having occurred during the passage.

THE Local Government Board have informed the town clerk of Dover that their medical officer will shortly visit the town to ascertain what provision there is for dealing with cholera cases that may arrive from the Continent.

WE regret to have to announce the death of Dr. Herbert Davies, Consulting Physician to the London Hospital, and Physician to the Bank of England. We hope to give an obituary notice of the deceased in our next issue.

DR. HERON proposes to show at the next meeting of the Medical Society of London on Monday, the 12th inst., specimens in pure cultivation of the comma bacillus of Koch.

THE UXBRIDGE TRAGEDY.

BY ANTHONY A. BOWLBY, F.R.C.S.

THE case known as the Uxbridge tragedy is one presenting many points of medico-legal importance, the question to decide being whether certain wounds found on a dead body had been suicidally or homicidally inflicted. The result of the trial was the conviction of the prisoner for the murder of her husband. The account which follows has been written on my own responsibility, and does not in any way implicate Mr. Parrott, the other medical witness. Nevertheless, I may say that on almost all the main points we were entirely agreed. The circumstances of the case are briefly as follows:—

The deceased, James Gibbons, aged sixty-five, a perfectly healthy and prosperous man, lived with his wife at Hayes, Middlesex. He had been married thirty-seven years, but had no children. He had adopted, or at any rate undertaken

the care and education of, a little girl distantly related to him, and had had disagreements with his wife on this account. On Nov. 15th, 1884, he went into the country to see his adopted child, in the evening he returned to Hayes and walked home from the station with the station-master, a personal friend, who testified that he left him close to his own door somewhere about 10 P.M. He was seen to enter his house by his own servant-girl, but was not again seen alive; his wife and he were the only persons who slept at his house. Shortly before midnight the next-door neighbour was aroused by Mrs. Gibbons, who was dressed in her night-gown alone and who said that her husband had committed suicide. The neighbour returned to the house with Mrs. Gibbons and found the deceased lying dead on his face upon the floor of the bedroom in a pool of blood. Close to his side lay a revolver. Mr. Parrott of Hayes was at once sent for, and in a short time arrived at the house with Mr. Hathaway, his assistant. They found the deceased lying on his face on the floor with his left arm stretched out towards the door, his right arm doubled under him, and his feet towards the bed. On the side of the bed next which he lay was a depression, as though caused by someone sitting down; this depression was about half-way down the bed, and close to it the sheet was sprinkled with a few spots of blood; anyone sitting on the place indicated would have his right hand towards the pillow. There were no marks of a struggle having taken place, but close to the door the wall was marked with blood spots. A very large amount of hæmorrhage had taken place, and the clothes of the deceased were saturated with blood; he was partly undressed, and had on a shirt, jersey, and drawers. Mr. Parrott hastily turned the deceased on to his back, and found the three wounds to be presently described; life was extinct, but the body was quite warm. Turning to the wife, Mr. Parrott naturally asked, "How has this happened?" She replied that they had had a few words about the little girl who used to live with them, that the deceased had then taken the revolver from under his pillow, and, exclaiming that he could stand it no longer, had waved the weapon round his head and fired off four or five shots in rapid succession. When asked by Mr. Parrott whether she had not tried to prevent her husband from killing himself, she said that she had thrown her arms round his neck, and then had run downstairs. It may here be remarked that Mrs. Gibbons made at different times six different statements. In one she said that all the shots were fired after she left the room in a fright at seeing her husband seize the pistol, in another that one shot was fired whilst she was in the room, the others after she left it, and in the remaining statements she said that two, three, and, lastly, all four shots were fired whilst she was in the room. At one time she said she saw her husband fall, at others that after getting downstairs she heard him fall. At no time did she say that the pistol had gone off during a struggle, or that she herself ever obtained possession of it. The pistol found beside the deceased was a six-chambered revolver, about six inches in length; five chambers had been recently discharged, and the sixth was occupied by an old empty cartridge case which had become blocked. The six chambers could be fired in succession by a series of pulls at the trigger without recocking, but the weapon had not what is known as a "rebounding lock"—i.e., one which cocks itself as soon as the bullet is discharged. The chambers could only be rotated by either pulling the trigger or raising the hammer with the finger or thumb; they did not rotate automatically, so that, after a shot had been fired, the empty cartridge case alone lay in a line with the barrel, and no bullet could be fired until after the revolution of the chambers brought a loaded cartridge into position. Except when cocked, it required a very strong pull at the trigger to fire the weapon; each shot demanded a distinct effort and the exercise of some strength. In the room was found a box containing sixteen cartridges, each of which fitted the pistol; the bullets were about one-third of an inch in diameter.

An inquest was held on Nov. 18th and adjourned, to enable medical evidence to be called. On Nov. 20th Mr. Parrott and Mr. Hathaway proceeded to make a post-mortem examination, and their attention was at once directed to a wound in the back of the left shoulder, which had passed unnoticed by them when first called to the deceased. After a partial examination of the body, Mr. Parrott applied for leave to obtain further assistance, and, at his request, I completed the post-mortem examination with the assistance of himself and Mr. Hathaway. The deceased was a man of middle height, broad-shouldered, rather stout, and heavily built. The scalp presented two small contused wounds, such as might have been caused by falling against any hard blunt object; one of these was situated on the forehead, the other near the occipital protuberance. The calvaria was normal, as was also the brain. The extremities were in a natural condition; the viscera were generally healthy. The following wounds were found:—

No. 1. In the left cheek, in a line with the canine tooth, was a bullet wound. The aperture in the skin was oblique so as to indicate that the bullet had entered in a direction from right to left as well as from before backwards. The superior maxilla had been shattered, the missile passing beneath the malar bone and lodging against the mastoid process, deep amongst the muscles of the neck. The face for some distance around the aperture of entry was blackened by powder, but the hair was not singed as though the pistol muzzle had been placed in actual contact; it might well have been held at a distance of several inches. No. 2. Immediately beneath the left clavicle, two inches to the outer side of the nipple line, was a perfectly clean-cut circular bullet wound of entry. The wound was in a direction almost directly backwards, but a little downwards, passing above the first rib towards the scapula; the bullet was found lying in the substance of the subscapularis muscle. In connexion with this wound there had been most extensive and abundant hæmorrhage, and the blood had been driven far and wide into the surrounding tissues, extending along the brachial plexus, and under the sterno-mastoid as high as the submaxillary triangle, backwards into the subscapular region, and forwards beneath the pectoral muscle. Evidently there had been a large vessel wounded, and in the subclavian artery, in the track of the bullet, was found a sharply cut hole such as would be caused by a missile of the nature discovered. The fact that there had been some dissection of the parts before I found the injured vessel alone prevented me from coming to a definite conclusion that the hole had certainly been caused by the bullet; nevertheless, I felt but little doubt in the matter. The skin around this wound was not blackened, and bore no traces of powder marks. No. 3. On the left side of the chest, two inches to the outer side of the nipple, and about half an inch below its level, was a bullet wound of entry. This wound was not circular, but oblique, indicating an entry of the bullet from above and behind, as well as in a general direction from left to right. As the arm lay by the side a probe could not be introduced further than through the skin, and it was not until the arm was raised to a right angle or more from the trunk that a probe could be passed into the thorax. It was then found, on reflecting the skin, that the fourth rib had been cleanly punctured by the bullet in an oblique manner. On removal of the sternum the anterior mediastinum was found full of blood—to use the words of Mr. Hathaway, "the thorax was fairly swamped with it." In the anterior surface of the pericardium were two torn holes, and its cavity also contained a quantity of blood. An examination of the heart showed that the bullet had struck the right ventricle on its anterior surface close to the septum and near the apex, that it had entered the cavity of the ventricle, and that being roughened and flattened by its transit of the rib, and by the same means having its velocity lessened, it had not made a clean-cut aperture of entry and exit, but had ploughed up and torn away the muscular substance in its course, thus allowing a very free exit to the contained blood. The bullet had then traversed the diaphragm, and was found a little to the right of the ensiform cartilage in the left lobe of the liver and close beneath the abdominal wall. The general direction of this wound was *from left to right, from above downwards, and from behind forwards.* The aperture in the skin, the axis of the entry and of the exit wounds in the rib were also in a similar direction, and there was every reason to believe that the bullet had not materially deviated from the direction in which it was fired. Further, it was evident that at the moment the wound was inflicted the arm must have been raised from the side to a considerable extent, for not only did the skin wound not correspond with that in the deeper structures unless the arm was so raised, but had the arm been by the side at the time the wound was inflicted it is certain that a bullet entering two inches to the outer side of the nipple and half an inch below its level must have passed just *below the fifth rib* or even lower, whereas in this case the fourth rib had been wounded. The skin around the wound was neither scorched nor blackened by powder.

It is evident from the position and direction of this wound that to be self-inflicted the weapon must have been held in the *left* hand of the deceased. No. 4. In the back of the left shoulder, on a level with the first dorsal vertebra and three inches from the spinal column, was a bullet wound of entry. It was perfectly circular in shape, and a probe could be passed along the wound in a direction *practically directly forwards, but with the very slightest tendency upwards* as far as a point immediately beneath the skin in the front of the neck; here the bullet had lodged. The wound traversed soft tissues alone, being confined to the thick and fleshy part of the base of the neck; no important structures had been injured. It was evident that the weapon that had inflicted this wound had been pointed almost *directly forwards* from behind the back of the deceased, for the entry wound was circular, and the bullet had struck nothing that could cause it to deviate from its course. The skin around the wound was blackened by powder to a considerable extent.

The clothes worn by the deceased at the time of his death were drawers, shirt, and flannel jersey; they had all been washed before I inspected them, but not before they were examined by Mr. Parrott. Only the shirt and jersey presented any signs of injury by bullets. At the back of the left shoulder, in a situation corresponding with wound No. 4, the shirt presented a ragged, singed hole, the size of a five-shilling piece; a corresponding but smaller hole was found in the jersey. The marks of powder were limited to the edges of the hole in the shirt; there was no scattering of powder granules around. Bullet holes corresponding in situation to the wounds No. 2 and 3 occurred in both the shirt and jersey. Each of these holes when seen by Mr. Parrott on the night of the death of the deceased were small and sharply cut, but owing to the scrubbing at the wash had become rather ragged, and enlarged to the size of a threepenny piece. The shirt for several inches around each of these holes was thinly dotted with powder marks, widely scattered in an irregular fashion. There was, however, no burning or blackening.

In order to satisfy myself as to the distance at which these shots had been fired, I procured eleven of the cartridges found in the room where the deceased had died, and with them, and a pistol of exactly the same make as that which had been found beside the deceased, I fired experimental shots at distances varying from actual contact (with a piece of shirting and flannel, which were then thoroughly washed) to a distance of two feet. As a result of these experiments I concluded that: (1) Wound No. 4 had been inflicted with the pistol at a distance of about an inch or so from the shirt, and that the muzzle had not been actually pressed against the back; (2) wounds No. 2 and 3 had been inflicted with the pistol muzzle at a distance of about one foot from the shirt, and certainly not less than six inches.

My next endeavour was to determine if possible the sequence of the wounds. With regard to Nos. 1 and 4, I did not find anything sufficiently definite to warrant me in forming an opinion on this point. Wound No. 2, however (below the clavicle), had almost certainly been inflicted before that of the heart, for the force with which the blood had evidently been pumped into the tissues argued that at the time this shot was fired the heart was acting vigorously and the arteries were distended with blood, neither of which would have been the case after such a wound of the heart as I have described.

Next, as to the immediate cause of death. There was nothing immediately dangerous to life in either of the wounds in the face or shoulder. The amount of hæmorrhage in connexion with the wound below the clavicle, coupled with the certainty that a large vessel—almost without doubt the subclavian—had been injured, pointed to the conclusion that this wound of itself was dangerous to life and one which might well cause death from loss of blood. But the heart wound was without doubt the one of all the four most likely to kill. Considering, therefore, the torn nature of the wound, the ease with which blood could be poured out, and the vast quantity of blood found within the thorax, I concluded that either from the shock to the heart, from direct loss of blood, or from interference with the cardiac action by the pressure of the effused blood, or from a combination of all these, life could not be prolonged beyond a couple of minutes.

Having then considered the facts already detailed, it became necessary to consider whether the wounds were suicidal or homicidal. And first of all, putting aside for the time the wound in the shoulder, was it *possible* for the deceased himself to inflict the other three wounds, Nos. 1, 2, and 3? The first point to consider was whether, after the amount of injury inflicted by two of them, a man would yet have power left to fire the third shot. I have already stated that, in my opinion, the heart wound had been inflicted *after* that below the clavicle, and that there was nothing in the face wound whereby I could say in what relation it stood to any of the other injuries in point of sequence. But, naturally endeavouring to reconcile the injuries to the theory of suicide, I found no difficulty in allowing that the face wound also might have been inflicted before that of the heart, and thus the heart wound would be placed last of the three. This was evidently the most favourable arrangement if the case were to be proved to be one of suicide, for it did away with the necessity of supposing that an old man, after having fired one shot through a large vessel and another through his heart, inflicting such a wound as I have described, should yet be able to fire a third bullet into his face,- a supposition that appeared to me impossible of acceptance, and one which fortunately there was no reason to adopt in order to admit of the suicidal character of the injuries. Assuming, therefore, that the shots had been fired in the order of -1st, the face wound; 2nd, the wound below the clavicle; and 3rdly, the heart wound, I felt that, although highly improbable, it was yet not impossible for all three to have been self-inflicted. But an examination of the clothing placed things in a different light. I have already said that I had arrived at the conclusion that shots Nos. 2 and 3 had been fired at a probable distance of a foot, certainly at a distance of not less than six inches. But if anyone will take a revolver in his left hand, with his finger on the trigger, and place the muzzle in such a position that it shall point at a spot two inches outside the nipple-line and half an inch below that level, in a direction from left to right forwards and downwards, he will find that the muzzle cannot be separated more than an inch or two from the side. And then it must be remembered that any loose clothing, like a shirt, would also be pulled away from the body by the lifting up of the arm to at least a similar distance, so that it becomes impossible to get the muzzle of the weapon appreciably separated from the clothing. Was there, then, any other way of holding and firing the pistol so as to inflict this wound and yet to keep the muzzle at a distance of a foot or a little less from the body? I could find none; for although it is possible to fire a shot into the side by pulling the trigger with the thumb, yet, putting aside the improbability of such a proceeding, I found that if the elbow was raised to a level with the shoulder, as was the case when the wound in question was inflicted, then it was not possible to point the weapon in the necessary direction whilst keeping the muzzle at the requisite distance. The weapon had certainly not been discharged at arm's length, for, at a distance of two feet, the powder did not mark the shirt at all. These points can scarcely be thoroughly appreciated except with a pistol in the hand. Considering, then, the position and direction of the heart wound, together with the entire absence of burning or singeing of the shirt, and feeling certain that the weapon must have been held in close contact with the chest if the wound were suicidal, I arrived at the conclusion that the deceased himself had certainly not fired the shot through his heart. Having, then, considered the possibilities of the self-infliction of the three wounds in the front of the body, I will now turn to the wound in the back (No. 4). I have already shown that this must have been inflicted with the pistol in near contact and with the muzzle pointing directly forwards. Neither Mr. Parrott nor myself was able to place the pistol in anything like the position necessary for the infliction of such a wound on our own persons. Others who tried were similarly and completely unable; and, putting aside the gross improbability of such a wound being intentionally inflicted, I felt justified in saying that a stout and heavily-built man, even in his death-struggle, could not possibly cause the injury in question, and that the wound could not have been inflicted so long as the weapon remained in either hand of the deceased. I think this conclusion will be sufficiently evident to anyone who, like the twelve jurymen, tries to perform on himself the feat of placing and holding a pistol in the necessary position, more particularly if with his finger on the trigger. So far, then, I had arrived at the conclusion that two out of the four wounds were certainly not self-inflicted; and if they were not suicidal

the natural inference was that neither were the other two—the presumption being that the same hand had inflicted all *four*.

The next point to consider was the probabilities in favour of or against the theory of suicide which presented themselves to a medico-legal witness. First, was the deceased a man likely to make a desperate attempt upon his own life? The only evidence in support of such a theory was a *statement* by the prisoner to the effect that her husband had injured his head five years ago, and had complained of headache at various times since. In controversion of this *Mr. Parrott*, whose assistant had attended deceased at the time of the said accident, informed me that the injury had been a trifling one, and that, although he had himself frequently attended the deceased during the past few years for slight ailments, he had never heard him complain of his head, nor had he ever noticed any difference in his manner. The suggestion made by the prisoner was that her husband had been suddenly seized with a fit of mania, and that in this fit he had committed suicide. Now, I am quite prepared to allow that there is frequently no adequate cause to be found for suicide in cases where this crime has undoubtedly been committed, yet it is a most extremely rare thing for a man to reach the age of sixty-five years without at any time showing the least tendency towards mania or delusions, and then to be seized with a most sudden attack of frenzy, for it must be remembered that so late as an hour before his death he was well and strong, cheerful and happy. Then were the wounds, taken together, such as would be likely to be self-inflicted? I thought they were not, and for the following reasons:—1. It is extraordinarily rare to find so many as three or four wounds in cases of suicide, and the extreme diversity of their situation argued against the self-infliction of all of them. The man was certainly quite sane as lately as an hour before his death. If the wounds were self-inflicted, then this was one of the most determined cases of suicide on record. 2. The amount of injury caused by the first two wounds on the front of the body of the deceased rendered it in the highest degree improbable that he should fire yet another shot, not to mention the wound in the back. The pain and shock caused by the infliction of a single wound such as that which shattered the upper jaw would almost certainly satisfy most suicides unless they were absolutely mad, and another injury, with great loss of blood, such as that caused by wound No. 2, would more than double the improbability of the wilful infliction of a third wound. 3. The position and direction of the wounds were greatly opposed to the theory of suicide. Wound No. 1 had entered the face from right to left, and though it might possibly have been fired by the left hand, was presumably, if suicidal, inflicted with the right. Wound No. 3 could only have been inflicted with the left hand, a condition of things which argued a change of hands during the infliction of the injuries. Then, it is a most unusual thing for a man naturally right-handed, as was the deceased, to use a weapon of any kind with the left hand, and it will be remembered that if the pistol was under his pillow, as stated by his wife, it lay ready to his right hand. Again, the heart wound (No. 3) was in such a situation and direction as to make it extremely awkward and difficult for it to be self-inflicted under any circumstances. A man about to kill himself does not hold the weapon in such a position; for, if anyone will try holding a pistol against his side at the spot I have already indicated, pointing forwards and downwards, he will find his hand is rendered so powerless by the constrained attitude that he will have difficulty in pulling the trigger at all. But if, in addition, the previous shot had wounded the subclavian artery of the *left* side, as was almost certainly the case, the improbability of the *left* hand being used to fire the pistol is greatly increased. Every surgeon knows the numb and powerless feeling that follows on a sudden stoppage of blood to a limb. In allowing, therefore, the possibility of the self-infliction of all three of the above wounds, I felt that I had given the prisoner the benefit of whatever doubt existed, but could not conscientiously say that such infliction was at all probable. 4. The condition of the clothing around wounds No. 2 and 3 was adverse to the theory of suicide. Putting aside the possibility of holding the pistol at a distance whilst inflicting the heart wound, it is a well-known fact that suicides almost invariably hold the weapon in close contact with the body. If a man wishes to kill himself he does not hold the weapon at a distance of a foot; yet this was the most probable distance at which the weapon had been fired. 5. A fifth bullet which had been fired had missed the deceased, and was subsequently picked up in the bedroom. It is an extremely unusual thing for a man to completely miss himself when trying to commit suicide with a revolver.

At the trial the question naturally arose, "Could the wound in the back have been inflicted by accident?" First, could it have been caused during a struggle between the deceased and his wife for possession of the weapon? The evident reply to this was that it could not be so inflicted unless the wife herself had possession of the pistol (I have repeatedly insisted on the impossibility of its infliction so long as the weapon was in either hand of the deceased); and granted that she had possession of it, there was nothing in the character of the wound itself to give information as to whether the finger that pulled the trigger had pulled it accidentally or otherwise; it did not appear to me to be a question for a medical witness at all. Nevertheless, it is evident that the improbability of such a wound being accidental is very great, considering what must have been the position of the pistol. And it must be remembered that in none of her statements did the prisoner say that there had been a struggle, or that she had ever obtained possession of the weapon, or that a shot had been fired whilst she tried to stop her husband from killing himself. The next suggestion of the learned counsel for the prisoner was that after the deceased had fired the three wounds on the front of the body and face he dropped the pistol, and then falling backwards on to it, the cartridge exploded and the wound in the shoulder was inflicted. I declined to say that such an accident was absolutely impossible, but it was most improbable, for the deceased was found *lying on his face*, not on his back. And then in order to inflict such a wound it was evident that he must fall on the upright muzzle of the pistol balanced with its butt against the ground, for as the weapon lay flat on the floor the wound in question could not possibly be inflicted. Then there was another and almost insuperable objection to the possibility of such an accident, which, however, I omitted to mention in the witness-box. The revolver was not a "self-cocking" one; it had not a "rebounding lock." If, therefore, it had been dropped after the infliction of the heart wound, without being recocked, it could not explode, for, until recocked, or until the trigger was pulled, the empty cartridge case of the bullet last fired alone lay in contact with the barrel. In order to bring up a fresh cartridge it was necessary to "revolve" the cylinder containing it by cocking or pulling the trigger. Was it likely that the deceased, after inflicting three serious wounds—one at least fatal—would recock the pistol, drop it, and then fall so as to cause it to explode and inflict the wound in question? Most unlikely, even if not impossible, it seemed to me, especially if it be considered that had he wanted to fire another shot he could have done so by pulling the trigger without recocking. Lastly, the condition of the clothing over the back wound negatived this supposition; for I have already stated that it did not seem probable that the weapon had been fired whilst pressed close against the back, as would have been the case if the deceased had fallen on the muzzle of the pistol. Thus no sufficiently plausible explanation could be found in support of the accidental infliction of wound No. 4.

I have now detailed in full the whole of the medico-legal facts bearing upon the case, and have endeavoured to place before the profession the evidence, as far as Mr. Parrott and myself are concerned, upon which the prisoner was convicted of murder. I have no intention of dealing with any of the other evidence adduced at the trial. For my own part, I may say that a very anxious and lengthy consideration of the circumstances of the case in all its bearings fully convinced me that it was one of homicide, and I found myself quite unable to reconcile the facts with the theory of suicide. Whether or no the medical evidence, taken in conjunction with the other circumstances of the case, was sufficient to justify a verdict of "Guilty" is not for me to settle, but that verdict was one in which the presiding judge entirely concurred.

The case has excited much public interest, and many persons have expressed their doubts as to the correctness of the conviction. I think these doubts are readily explained. The position and direction of the wounds demonstrated by Mr. Parrott and myself on a plaster bust to the judge and jury, the explanation of medical points whose importance it

was not easy to grasp, was not the kind of evidence likely to be faithfully and correctly reproduced by the newspaper reporters. The consequence was that the most absurd statements were put into the mouths of the medical witnesses, and in no paper that I read did my own evidence occupy more than a dozen lines; indeed, one journal which devoted two entire leaders to the case, and especially to the medical evidence, did not report a single word uttered by myself in the witness-box. Now, personally, this is a matter of entire indifference, except that it has exposed me to the attacks of innumerable correspondents, and before I leave the matter I would merely say that had I been one of the general public, I should certainly have felt some of the dissatisfaction which found vent in the press, though I think also I should have had sufficient confidence in "trial by jury" to rest assured that there was more evidence than appeared on the surface.

But while I am not surprised at the feeling expressed by the reading public, I confess I had felt pretty confident that members of my own profession would withhold their condemnation, if not their opinion, until they were in possession of the real facts of the case, and I am only sorry to find I have been mistaken. There has apparently been a prevailing impression, gathered whence I know not, that in order to prove the case one of suicide it is necessary to presuppose the ability of the deceased to fire other shots after the wound in the heart. If anyone will refer to what I have written, he will find that there is no necessity for anything of the kind. Well, with this idea apparently fixed in their minds, numerous correspondents have detailed at length, as singular and extraordinary, cases in which a man has lived for a variable time, and possessed the power to perform various actions after a heart wound. They also kindly conclude that the medical witnesses did not realise the possibility of such an occurrence. Now, the very fact that these numerous writers each considered his own case a singular one showed very plainly that the ignorance was on their side, for every surgeon is, or should be, aware that the cases of heart wounds that have not proved immediately fatal may be counted by dozens, not by units, and, further, that complete recovery may ensue after such injuries. Lastly, the same class of correspondents, most, I am glad to say, not in the medical profession, speak of all heart wounds in general, and assume that because one may not be immediately fatal therefore all the others may run a similar course,--a deduction which is simply absurd. But it is not a material point in the present case whether the heart wound was immediately fatal or no, and there appears to me to be no reason for raising a discussion on what is simply a side question.

In conclusion, I may say that I should be very glad if this report induces those who have had greater experience than myself in medico-legal work to express their opinions on the result of the trial and on the many points for consideration presented by the medico-legal aspect of the case. For my own part, I may say that I shall be happy to furnish any other information in my power.

*** Although Mr. Bowlby declines to implicate Mr. Parrott by any of the statements contained in his elaborate account of the medical bearings of the Uxbridge tragedy, one cannot fail to recognise in the report a general and inclusive defence of the position taken by these gentlemen at the recent trial of Elizabeth Gibbons. It is neither our wish nor intention to go behind the facts given by Mr. Bowlby with such minuteness of detail, we had almost said with reiteration, but to some of his deductions and "presumptions" we now, as heretofore, respectfully but decidedly take exception. On the question of motive there seems a complete absence of anything that could reasonably be considered adequate to the act, unless it be the impulse of a disordered brain, no longer under the governance of the will; in which case, be the result suicide or homicide, the person who committed the crime could not be held responsible for it. Previous to the fatal night there does not appear to have been noticed in either Mr. or Mrs. Gibbons such moral or mental obliquity as to furnish reasonable suspicion that either of them contemplated the arbitrament of the revolver. It then becomes necessary to look further afield for some indication of the direction in which the probabilities lie, and on this head it transpires that the deceased belonged to a family in whom at least one individual is said to have evinced suicidal tendencies. We are willing, if Mr. Bowlby desires, to admit that "the injury to the head which Mr. Gibbons had suffered some five years previously could not be proved to stand in causal relationship to a sudden outbreak of insanity," although the history of medicine contains not a few instances in support of the assumption that it might. On a review of the antecedents of the deceased and the convict we fail to see that the latter was the more likely of the two to be the victim of an impulse or desire to destroy life. Thus much for motive. Now as to the alleged sixfold variation in the statements of Mrs. Gibbons, with regard to the nature and sequence of events that happened between the firing of the first shot and her impassioned appeal to her neighbours for help. Can it be contended for one moment that discrepancies ought not to arise? It would be an interesting psychological study to contemplate the varying moods of a mind distraught with grief for an irrevocable deed of blood, harassed by fears for the future of life, and tossed in the eddy of perpetual unrest. Is it to be wondered at, then, that the knowledge of what took place in those eventful moments should be confused in the disturbance of mental equilibrium, consequent on the experience of such a disaster? And yet Mr. Bowlby sees reason for drawing conclusions unfavourable to Mrs. Gibbons on account of her verbal inconsistencies; at the same time that he seeks in her silence as to the occurrence of a struggle further signs of her guilt. It is possible to weaken an argument by proving too much. We do not say that the story and demeanour of an accused person on different occasions are valueless when estimating the likelihood of innocence or crime; but we unhesitatingly assert that the system under which such a person is interrogated and otherwise examined in this country is a burlesque on common sense and a travesty of justice. Concerning the bullet wounds, Mr. Bowlby says that Nos. 1, 2, and 3 were possibly suicidal, and No. 4 was possibly accidental, though it could not have been self-inflicted. We may at once say that we accept this interpretation as correct. The fact of the fifth shot missing the body of the deceased goes for little, since that can easily be accounted for by its being diverted from an intended course during a struggle, or fired aimlessly by the victim already in the throes of death. The grounds for Mr. Bowlby's belief that the subclavian artery was wounded before the heart consist mainly of the fact that a quantity of blood was pumped into the tissue surrounding the track of the third bullet. There is some cogency in this reasoning. At the same time it must be borne in mind that the heart acted with vigour for several strokes after the perforation of the left ventricle, for we learn the anterior mediastinum was filled, and the chest "swamped with blood." We doubt if the hæmorrhage from the subclavian artery would be sufficiently sudden and profuse to prevent, through numbness of the hand, a further shot being fired. The all but certainty that the barrels were discharged in rapid succession must not be lost sight of when estimating the probabilities as to the order of events, and the question of homicide or suicide. It is beyond cavil that a series of fatal wounds may be self-inflicted, even though weapons have to be changed from one hand to the other, for the immediate shock of the injury is inversely proportionate to the mental excitement or determination, as witness the records of military surgery. The experiments devised by Mr. Bowlby for the purpose of forming an opinion of the distance at which the shots were fired were well directed, but, to our minds, the disturbing elements were too great to warrant more than an approximate estimate. To arrive at anything definite, a much more extended and varied series of operations would be necessary. Mr. Bowlby substantially repeats that we have fallen into

the error "that in order to prove the case one of suicide, it is necessary to presuppose the ability of the deceased to fire other shots after the heart was wounded." Our answer to the indictment is to be found in THE LANCET of Jan. 3rd, p. 40. In conclusion, we may say generally that we still think there is a reasonable doubt whether the act whereby Mr. Gibbons lost his life was one of deliberate murder, impulsive homicide, justifiable homicide, or suicide. The great difficulties encountered in the investigation amply justified the public and the profession in opposing the doctrine of infallibility of the medical witnesses.—ED. L.

THE OUTBREAK OF CHOLERA AT YPORT.

THE precise details of the outbreak of cholera at Yport in October and November last are of especial interest, because the cases which took place there were the nearest ones to this country of those which occurred during the widely spread epidemic of 1884. Several different versions have been given as to the cause of the outbreak, and hence Dr. Gibert of Havre, who was officially appointed to investigate the outbreak and to take measures to prevent its spread, has now placed a complete history of the circumstances on record. On the 7th of September the *Louise-Marie* entered the port of Cette, having had no cases of sickness on board during the voyage from Newfoundland. The crew, on landing, committed excesses and contracted cholera, two of the cases terminating fatally in Cette. Although seven others had suffered from specific cholera, the captain allowed the crew to leave and to traverse France by rail without taking any precautionary measures whatever. One, being attacked with cholera during the journey, was taken out of the train at Tarascon, where he died, but his baggage went on. The remainder reached Fécamp, where their clothing and effects would have been submitted to an efficient disinfection by sulphur fumes had it not been that the Sister of Mercy in charge of the stove prepared some useless compound instead of using the unmixed sulphur. Two of the crew arrived at Fécamp on Sept. 28th. One, named Bazile, had suffered from an attack of cholera at Cette, and next day he, with the assistance of a sister-in-law and brother, wrung out his clothes &c. in water, the dirty liquid being allowed to run away down the street for a distance of fifty metres. On the 4th of October the sister-in-law, named Candelier, though suffering from diarrhœa, washed the same articles, and on returning from this task was seized with marked symptoms of cholera and died in a few hours. On the 8th of October another woman, Lemonnier, was also seized, and died rapidly. Seven persons were attacked and died between Oct. 5th and 22nd, and it was only at this date that the circumstances were made public, and that Dr. Gibert received instructions to visit Yport. Dr. Gibert's description of Yport confirms all that has been said of this dirty little place, with its narrow streets and lanes, its dwellings with mud floors, rather resembling caves than houses, and its general state of sanitary neglect. Every effort was at once made to prevent extension of the disease, by shutting up and disinfecting infected premises, burning bedding and clothes, isolating the sick, and adopting measures of cleansing. One woman who had nursed a fatal case at Yport conveyed the disease to Mont Perthus, near Fécamp, and some five kilometres from Yport, but complete isolation of the case prevented any further spread. In all there were forty-two cases, of whom eighteen died and twenty-four recovered.

Dr. Gibert is anxious throughout his description to show that the disease was neither aerially communicated to Yport nor due to spontaneous origin, and he arrives at the conclusion that the infected articles brought by the sailor Bazile were the immediate cause of the outbreak, the effluent water resulting from the process of washing them having in the main communicated the disease down the street. Yport appears to contain every element for the propagation of an infection such as cholera when once brought in; and it says much for the organisation established that the spread was a comparatively limited one. Water appears to have had nothing to do with the propagation of the disease, but this was so only because no one in Yport ever drinks water.

One other point of interest is adverted to. It is evident that the outbreaks, both in Toulon and Paris, have by certain persons in those cities been regarded as of a local character or as due to aerial contamination. Dr. Gibert, however, points out that in such populous places it is impossible to exclude with certainty all sources of importation, and that it is rather in small villages, like Yport, that undeniable evidence as to the method of the propagation of such a disease as cholera is likely to be met with. Pointing, then, to the connexion of the Yport outbreak with infected clothing, he calls attention to the circumstance that the baggage of the man whose journey was arrested by his fatal attack at Tarascon was allowed to remain amongst the other luggage in the train, &c., and ultimately found its way to the Lyons terminus in Paris. Was the baggage of this cholera infected man the means of conveying the disease to the capital? he asks. All such sources of infection must certainly be excluded before it can be admitted that air, after traversing nearly the whole of France without producing any mischievous results, could have communicated infection to Paris.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

A SPECIAL general meeting of the Fellows will take place on the 10th instant, in order to consider the proposed alterations in the Supplemental Charter and Bye-laws of the College. The proposed amendments refer to the casting vote of the chairman of a meeting in case of an equality of votes, to the granting of diplomas to women, and the mode of electing examiners. In connexion with the latter, the Council has considered the propriety of cancelling the words of Clause 11 of the Charter, which prohibit professors and lecturers from being examiners. Upon the recommendation of the Education Committee it has been resolved to remove the prohibitory words, and, in order to provide for a more frequent change in the *personnel* of the Court of Examiners, and to obviate any danger of a preponderating influence of any school being established in the Court, has adopted the following Bye-law in substitution for those now in force, as to election and tenure of office of examiners:—

"Examiners shall be elected for one year, either as Surgical, Anatomical, or Materia Medica and Chemistry Examiners. On the first Tuesday in May the Council shall elect examiners to examine candidates for Fellowship and Letters Testimonial; also examiners to examine candidates for the diploma in Midwifery; and examiners to examine candidates in general education. No person who is engaged in private teaching shall be eligible as examiner, and if any examiner shall engage in such teaching it shall render his election null and void. No examiner shall hold office for more than three consecutive years, nor be eligible for re-election until after the lapse of one year."

The Council has also adopted the following resolution:—"Not more than two teachers connected with any one school or hospital shall be eligible to obtain seats on the Board of Examiners."

Public Health and Poor Law.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Taunton.—The special report on the Taunton sanitary hospital goes to show that this institution continues year by year to gain the appreciation of the public, and that there is not merely a great increase in the number of patients admitted, but that there has been a considerable increase in the number of paying patients. During the previous three years the average number of admissions was 53; in the past year it was 127; the diseases including 46 cases of scarlet fever, 71 of diphtheria, and 9 of enteric fever. Under Dr. Alford's supervision this hospital, which has been provided by the urban and rural authorities jointly, has done a vast amount of good in preventing the spread of infection, and the cost of its maintenance has unquestionably prevented other, if not greater, expenditure.

West Sussex.—The report for the combination of sanitary districts for which Dr. Kelly acts as medical officer of health is necessarily a bulky one. The area covers about 524 square miles, and contains a population not far short of 100,000. The general death-rate in 1883 was 14·8 per 1000, Horsham standing at one extreme with a rate of 12·7, and Petworth at the other with 18·0. The infantile death-rate is small, the rate for children under one year amounting to only 88 per 1000 births, as opposed to a corresponding rate of 137 for England and Wales generally. The zymotic rate is also low, standing as it does at 1·4 per 1000 living. An interesting account is given of an outbreak of small-pox in the Midhurst Union and of the measures of prevention which were adopted. There were originally two centres of infection, the disease having been contracted in connexion with rag-picking. Failing adequate hospital provision, Dr. Kelly in each case took one of the infected cottages and used it as an isolation hospital, vaccination and temporary isolation being enjoined on those who were hitherto not infected. Of those who were revaccinated none contracted the disease although some assisted in the care of the sick. But all were not vaccinated, and since some extension of the disease occurred, a tent hospital encampment was rapidly organised on Stedham Common, the result being that by the aid of these measures the outbreak was stamped out. The details given under the headings of the various districts show that a large amount of useful sanitary work is in progress, and for the information of skilled observers very complete meteorological and other observations are set out in detail.

Fulham.—The Fulham district has an estimated population of 138,000 inhabitants; the birth and death-rates during 1883 were respectively 36·3 and 18·9 per 1000 living. No small-pox occurred in the district during the year. Scarlet fever caused 43 deaths, and 56 cases were removed to the Western District Hospital. It is estimated that 860 cases occurred, but only 172 were known to the sanitary authority, and in those cases only were they able to carry out measures of disinfection. During 1882 there was no typhus in the district, but in 1883 36 cases came under notice, most of them being connected with the outbreak which occurred at Nazareth House, and which we commented on at the time. Amongst the points needing further sanitary action are—the removal of piggeries, some 500 of which are in places unfit for such purposes; the completion of new regulations as to houses let in lodgings; and the provision of a suitable mortuary.

Malton Rural District.—Dr. Young reports the occurrence of a diarrhœal outbreak amongst the consumers of a certain water-supply which was derived from a well to which soakage from manure was found to have access. In connexion with certain occurrences of diphtheria, typhoid fever, &c., improvements have been effected as to privies, the disconnexion of sink-pipes, &c., and impure water-supplies have been stopped. The annual death-rate for 1883 was 14·8 per 1000.

Willesden Urban District.—This increasing suburban district had in 1883 the lowest death-rate since its formation—namely, 15·4 per 1000 living. Diarrhœa caused some special mortality in the autumn, and Mr. Branthwaite looks to regulations as to houses sub-let in lodgings for the removal of some of the more obvious conditions which led to the prevalence. Cases of small-pox, scarlet fever, and enteric fever were isolated in hospital, but the sanitary authority are again pressed to secure a site on which a suitable hospital, adapted to the circumstances of the district, may be erected. The cow-sheds, slaughter-houses, bake-houses, and premises used for the manufacture of food have all received special attention during the systematic inquiries which have been made. A mortuary for Kilburn is a pressing want; and a scheme of drainage, for which a loan has been secured, remains to be carried out.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6387 births and 4195 deaths were registered during the week ending the 3rd inst. Both these numbers considerably exceeded the average numbers during the year, the excess being in great measure due to arrears of registration from the previous week. The annual death-rate in these towns last week was equal to 25·0 per 1000, against rates decreasing from 24·4 to 20·2 in the preceding four weeks. During the thirteen weeks ending the 27th ult. the death-rate in these towns averaged 21·4 per 1000, against 23·0 and 21·2 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 20·0 in Plymouth and Huddersfield, 21·2 in Portsmouth, and 21·4 in Derby. The rates in the other towns ranged upwards to 29·3 in Newcastle-upon-Tyne, 32·5 in Preston, 32·9 in Norwich, and 34·6 in Cardiff. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 308 and 311 in the preceding two weeks, rose again to 375 last week; these included 95 from whooping-cough, 78 from measles, 65 from scarlet fever, 36 from diphtheria, 35 from "fever" (principally enteric), 33 from small-pox, and 33 from diarrhœa. These diseases caused the lowest death-rates last week in Portsmouth and Brighton, and the highest in Leicester, Newcastle-upon-Tyne, and Cardiff. Whooping-cough caused the greatest mortality in Birmingham and Preston; measles in Leicester and Cardiff; scarlet fever in Sunderland, Halifax, and Newcastle-upon-Tyne; and "fever" in Sheffield and Norwich. The 36 deaths from diphtheria in the twenty-eight towns included 20 in London and 2 in Liverpool. Small-pox caused 58 deaths in London and its outer ring of suburban districts, and not one in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1026 and 1079 on the preceding two Saturdays, declined to 1013 at the end of last week; the admissions in the week were 171, against 244 and 161 in the previous two weeks. The Highgate Small-pox Hospital contained 92 patients on Saturday last, 15 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined steadily in the preceding five weeks from 511 to 370, rose again last week to 537, but were 39 below the corrected weekly average. The causes of 120, or 2·9 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Portsmouth, Norwich, Plymouth, Derby, and Huddersfield. The largest proportions of uncertified deaths were registered in Halifax, Hull, Sunderland, and Salford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 26·9 and 29·6 per 1000 in the preceding two weeks, further rose to 30·7 in the week ending the 3rd instant, and exceeded by 5·7 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 18·8 and 22·7 in Edinburgh and Leith, to 36·6 in Paisley and 39·0 in Glasgow. The 741 deaths in the eight towns showed a further increase of 50 upon the numbers in the previous two weeks, and included 38 from measles, 27 from whooping-cough, 14 from scarlet fever, 14 from diphtheria, 10 from "fever" (typhus, enteric, or simple), 7 from diarrhœa, and not one from small-pox; in all, 110 deaths resulted from these principal zymotic diseases, corresponding with the number in the previous week. These 110 deaths were equal to an annual rate of 4·6 per 1000, which exceeded by 2·4 the mean rate from the same diseases in the twenty-eight English towns. The 38 fatal cases of measles showed a further

increase upon recent weekly numbers, and included 30 in Glasgow, 5 in Dundee, and 3 in Aberdeen. The deaths from whooping-cough, which had been 30, 25, and 26 in the previous three weeks, were 27 last week, of which 13 occurred in Glasgow and 4 in Leith. The 14 deaths referred both to scarlet fever and to diphtheria included 9 and 6 respectively in Glasgow. Of the 10 deaths from "fever," showing a decline from the numbers in the previous two weeks, 5 were returned in Glasgow, 3 in Edinburgh, and 2 in Aberdeen. The 7 deaths attributed to diarrhœal diseases were considerably below the average. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had steadily declined in the preceding four weeks from 231 to 174, rose again last week to 203, and exceeded by 95 the number returned from these diseases in the corresponding week of last year. The causes of 125, or 16·9 per cent., of the deaths registered in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 34·1 and 26·6 per 1000 in the preceding two weeks, rose to 38·5 in the week ending the 3rd inst. During the thirteen weeks ending the 27th ult. the death-rate in the city averaged 29·4 per 1000, the mean rate during the same period not exceeding 19·8 in London and 19·7 in Edinburgh. The 259 deaths in Dublin last week showed an increase of 81 upon the number in the previous week, owing in great measure to arrears of registration from the previous week; they included 11 which were referred to scarlet fever, 7 to "fever" (typhus, enteric, or simple), 3 to measles, 3 to diarrhœa, and not one either to small-pox, diphtheria, or whooping-cough. Thus 24 deaths resulted from these principal zymotic diseases, against 18 and 13 in the previous two weeks, and were equal to an annual rate of 3·6 per 1000; the rates from these diseases last week were 2·2 in London and 1·5 in Edinburgh. The fatal cases of scarlet fever and of "fever" in Dublin last week exceeded the numbers returned in any recent week; and those of measles and of diarrhœa also showed an increase. Seventeen inquest cases and 12 deaths from violence were registered within the city, and 81, or nearly a third of the deaths, were recorded in public institutions. The deaths both of infants and of elderly persons exceeded any recent weekly numbers. The causes of 38, or nearly 15 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

CHARCOT'S DISEASE.

To the Editor of THE LANCET.

SIR,—In your report of the few remarks which I made at the Clinical Society on the subject of Charcot's disease, you credit me with having said in answer to the President that "I agreed almost completely with Dr. Pye Smith that a new disease was impossible." I did not say so. On the contrary, I said that I did not regard a new disease as an impossibility, but that there was not sufficient evidence to warrant us in regarding this as one. A new disease is a thing whose existence I should be very chary of admitting; and little short of absolute demonstration would convince me of its existence. In the present instance there is not such demonstration; and I see no valid reason for making an exception in its favour. But to say that it is impossible for a new disease to occur is a forecast into the future which I equally see no valid reason for making. Twenty years ago none of us knew anything about tabes dorsalis. When Duchenne first described locomotor ataxy, physicians did not say "Oh! here is a new disease; such a malady never existed before." No, they only said, "Duchenne is quite right; these symptoms have entirely escaped our observation; the disease is quite different from ordinary paralysis; and it is clear that none of us observed this before." In so doing, physicians have set to surgeons an example which they might well follow.

The evidence in support of the view that Charcot's arthropathic limb is peculiar, and is essentially and causally connected with tabes dorsalis, seems to me overwhelming; but it would have been unreasonable to have expected surgeons (for naturally this condition of limb would come under the notice of the surgeon rather than the physician) to have recognised and described this peculiarity, and its essentially distinct nature, before physicians had recognised that special change in the posterior columnæ of the cord, and the resulting loss of coördinate movement, which, if Charcot's views are correct, is a necessary precursor of the local change in the limb. In other words, it was almost impossible that surgeons should have recognised the condition of limb which Charcot has described before physicians had recognised the form of paralysis which Duchenne described, and which is a necessary precursor to Charcot's disease. The fact that our museums contain no specimens of Charcot's arthropathic limb does not prove it to be a new disease, any more than the absence from the same shelves of specimens of tabes dorsalis proves that that disease did not exist before the days of Duchenne.

I am, Sir, your obedient servant,

Jan. 3rd, 1885. T. J. MACLAGAN, M.D.

TREATMENT OF INTESTINAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—Mr. Banks has taken much unnecessary trouble in endeavouring to refute the charge implied in my letter, for, after all, his reply shows that he still looks upon Mr. Thomas as merely one of many authors who have laid down the so-called "rest, opium, and starvation" treatment in intestinal obstruction. His letter, however, has entirely acquitted him of having intentionally overlooked Mr. Thomas's claim to the exposition of these principles properly so-called, for it is quite clear that he has not read that gentleman's work, and further, that he is quite ignorant of what the Sydenham method of treatment, as laid down by him, really involves. Mr. Banks writes of the rest, opium, and starvation treatment as taught by Laycock, Christison, Miller, Brinton, Cameron, Waters, Treves, and Banks, as if they were the same as that taught by Sydenham, utterly ignoring the fact that it is the wide difference between them upon which Mr. Thomas has been the first and the only one to lay such stress.

The grand distinction between the form of treatment by modern practitioners and that of Sydenham, as revived by Thomas, is that while in the former the principles of rest, opium, and starvation are applied in name only, in the latter they are a reality; in the former they are only introductory to, or supplementary to, other antagonistic agencies, while in the latter they are insisted upon from beginning to end without qualification or modification. The authors quoted by Mr. Banks advocate plans of treatment entirely antagonistic to the Sydenham teaching. They do not believe in absolute rest. Mr. Banks himself, in support of Mr. Treves, advocates nutrient enemata. Sydenham, as quoted by Thomas, says: "A mere sugar-and-milk clyster may undo all that the paregoric has done." Mr. Banks, as a physiologist, surely knows that an enema, nutrient or otherwise, increases peristalsis not merely below, but above, the seat of obstruction, and unless he believes that increased peristalsis is consistent with rest, he is knowingly violating the very principle of rest—and why? Simply to avoid the fancied danger of starvation, for the fact that the Sydenham and Thomas method of feeding fairly maintains vitality is wonderfully borne out by Mr. Greves, who told us at the meeting of the Medical Society that the child actually gained in weight. If Mr. Banks had ever appreciated Sydenham's views of starvation, he would not have written what he has about the necessity of giving sustenance to prevent death from exhaustion. Sydenham clearly laid down that it was the pain and lesion itself which killed the patient, and not the want of food.

Enemata are not the only remedies which, though antagonistic to rest, are added to the Sydenham method in such a way as to defeat its objects. Belladonna is given with opium—its antidote. Calomel is given, and castor oil, and although I am much indebted to Mr. Banks for reminding me that the former is used as a remedy for irritability of the stomach, I fail to see what either that or the simple constipation to which he alludes has to do with the subject in hand. Even Mr. Treves, I repeat, nowhere alludes to the

Sydenham method of treatment, nor to the quality of the diet as an all-important element, permitting the safe use of opium which he advocates. If, as Mr. Banks says, Mr. Thomas did not claim originality, all I can say is that he has not claimed his due. I find on comparing their works that Sydenham taught that laudanum was essential, with control of diet; while Mr. Thomas teaches that the quality of the diet is all-important, and the sedative only supplementary.

Mr. Banks has stated his own views on the subject, and his faith in rest and opium is not too great to prevent him from saying that they "are mightily unsuccessful in really serious cases, however much they may do for those which would have got well under any treatment," which is tantamount to reducing the value of such treatment to a nonentity.

To sum the subject up, I contend that, until some authority has shown that before 1874 he has treated cases of obstruction according to the true Sydenham method *ab initio ad finem* without modification or addition, the credit of rejuvenating the true and original rest, opium, and starvation treatment is due to Mr. Thomas alone, and until the treatment he advocates has been faithfully tried by the profession it cannot be said to be the recognised treatment; and I challenge Mr. Banks, or anyone, to show the publication of any one case so treated from the time of the death of Sydenham to the first appearance of Mr. Thomas's work.

Let me say, in conclusion, that I am sorry Mr. Banks has taken such a personal view of the matter; I certainly never intended to hurt his feelings, although I fail to see with him that the fact of my being an old pupil of his should restrain me from entering a friendly protest on behalf of one whom, though not a fellow professor of Mr. Banks, I am proud to acknowledge as an old teacher.

Yours faithfully,

Liverpool, Jan. 5th, 1885. CHARLES E. STEELE.

To the Editor of THE LANCET.

SIR,—Mr. Banks correctly informed you that at the discussion on Intestinal Obstruction I laid no claim to the discovery of the physiological method of treating such ailments. True as this may be, I had come to my present opinion, and carried it out in practice, many years before I was aware that Sydenham had in a very great measure anticipated me. It was only when the present Professor of Surgery induced me to publish my views that I found that Sydenham had anticipated me, and he alone. Between Sydenham and myself a void exists, and there are no records to fill the gap. I am, Sir, yours faithfully,

Nelson-street, Liverpool, Jan. 3rd, 1885. H. O. THOMAS.

COCAINE AS A LOCAL ANÆSTHETIC.

To the Editor of THE LANCET.

SIR,—The following case may be interesting to some of your readers, as it illustrates the value of this new remedy. Having a fortnight since had occasion to divide the cervix uteri with Küchenmeister's scissors, in a woman with extremely sensitive vulva, and who refused to take an anæsthetic, I painted the entrance with a 10 per cent. solution of the hydrochlorate of cocaine five minutes before operating. It answered admirably, entirely removing the pain, and also completely relieved the spasm as much as if she were under chloroform, thus adding much to the ease of the operation.

I am, Sir, yours truly,

J. BRAXTON HICKS.

George-street, Hanover-square, W., January 2nd, 1885.

To the Editor of THE LANCET.

SIR,—A man aged eighty, with an epithelioma of the lower lip, which had been increasing rapidly for a year, consulted me as to what it was and what must be done. I immediately told him that it must be removed; but on stethoscopic examination I found he had extensive cardiac disease. Not thinking him a fit subject for chloroform, I wanted to operate without its administration, but he objected. I then thought of giving cocaine a trial; and having explained to him what I should do, he readily consented. Yesterday, December 29th, he came to my house. Having injected hypodermically three minims of a 4 per cent. solution of hydrochlorate of cocaine on each side of the epithelioma, I allowed six or seven minutes to elapse, when local anæsthesia was complete. With the assistance of my father I then operated, and during the time the man never flinched once. Afterwards on asking if he felt any pain, his answer was, "I hardly felt anything at all." He remained some little time, but we could not perceive any constitutional effects. On seeing him to-day he says he never felt better in his life, but about two hours after leaving my house yesterday he had pain for some time, which, however, passed away during the night. Had it not been for the solution of cocaine, this man would never have been operated on, and in a very short time he would have died. In cases of minor surgery when I have an opportunity of using the solution of cocaine I shall certainly do so; its simplicity and absence of risk over chloroform seem to me very great.—I am, Sir, yours faithfully,

LALANDE HAINS, L.R.C.P. & S. Ed.

Totnes, Dec. 30th, 1884.

To the Editor of THE LANCET.

SIR, Of the value of cocaine in operations on the eye, larynx, &c., there has been abundant evidence, but I have read little of its action upon the vaginal mucous tract, and of the help it gives in dealing with painful affections of that region, and therefore I think the case I am about to relate will prove of interest. A married lady has been under my care for some time suffering from chronic endometritis, with ulceration and erosion of the os uteri and a granular condition of the vaginal mucous membrane. Digital examination is simply agonising to her, and of late, in order to use the speculum for the purpose of cauterisation, &c., it has been necessary to put her under chloroform, as it was absolutely impossible to pass the speculum, the pain and vaginismus being so great. I determined to try the effect of cocaine in the form of suppository and in solution, prepared for me by Mr. Martindale. I passed a suppository containing one grain of the muriate of cocaine well up to the os; after five minutes I painted the vaginal orifice with a 4 per cent. solution of the same drug, and after another five minutes I proceeded to pass the speculum. The freedom with which I could do this was nothing short of marvellous, and what would previously have been unbearable was borne with comparative comfort. There was certainly a little pain felt, but even this I think at a future examination I shall obviate, (1) by waiting rather longer than ten minutes for the suppository to melt, as I found on introducing the speculum some of the suppository still unmelted, and (2) by using two suppositories instead of one, the tract of mucous membrane being so large. I think it very necessary to paint the vaginal orifice with the solution, in addition to using the suppository, as the vaginismus and the consequent opposition to the entrance of the speculum into the vagina are thereby done away with.—I remain, yours very truly,

Penryn, Cornwall, Jan. 8th, 1885. JAMES BLAMEY.

THE PROPOSED NEW TEACHING UNIVERSITY FOR LONDON.

To the Editor of THE LANCET.

SIR,—I have read with much interest and no little anxiety all that has been written in THE LANCET with reference to the establishment of a teaching university in London. Sympathy with the object proposed, and desire for the success of the undertaking, are, I doubt not, common to all the members of the medical profession; and with regard to the faculties of arts and science, I have had the assurance from many quarters that there is a deep and widespread feeling that the regulations of the existing university are by no means adequate to the growing educational activity of the country. If I rightly understand the matter, the object, as far as medical degrees are concerned, is to compete with the vigorous and flourishing universities of Scotland. Now, in order to understand clearly the difficulties in the way of accomplishing this, and the dangers to be avoided, it would be well to inquire into the causes which have led to the large afflux of medical students to the northern universities, and more especially to that of Edinburgh. As I am somewhat intimately acquainted with the regulations of the universities both of London and of Edinburgh, and as the directions published in the

calendars give a very imperfect idea of the working of these regulations, I propose to point out one or two differences which have, I think, conduced to the result referred to above.

First and foremost, there is the matriculation examination at the London University, which embraces a wide variety of subjects, and which is conducted on the all or none principle with the most charming impartiality. I have known candidates present themselves three or four times for this examination, and ultimately, while passing in those subjects in which they had failed before, fail in one or two of those in which they had previously satisfied the examiners; and the same has happened, even to a greater extent, in the science and arts departments. Now, at Edinburgh the medical preliminary examination can be taken one subject at a time, if the candidate so prefers; and provided he has passed in the subjects required for registration he can proceed to attend medical classes and pass at any time during his medical curriculum in those subjects required by the university over and above what are necessary for registration, it being always understood, of course, that he is not to be admitted to any professional examination until these additional subjects have been mastered. There is no doubt that many do pass in all the subjects at once, but a very large number do not, and the latter not unfrequently surpass the former in the ease with which they grasp and assimilate the purely professional parts of their course. The two kinds of study require mental endowments of two different kinds, and it not unfrequently happens that these are not combined in the same individual. A young friend of mine, who found the greatest difficulty in mastering the elements of mechanics, and who was nearly giving up the attempt in despair, shortly afterwards proved himself a sound anatomist and a brilliant dissector, and passed his professional examinations not only with credit, but also with distinction. While he had to do with abstractions relating to nothing in particular, his mind was shrouded in a mist which nothing could dispel; but when hand and eye and mind came to act together in the acquisition of knowledge, then he found that he was not quite the "duffer" which, in his dejection, he had often called himself.

At the preliminary scientific examination at the London University the papers in physics are the great stumbling-blocks to medical students, and most people who know anything of the requirements of medical study will admit that they are unnecessarily severe; and here also there is the same rigid adherence to the plan of plucking a candidate in all his subjects because he has proved himself weak in one. At Edinburgh the first professional examination embraces only botany, zoology, and chemistry; and at this examination, if a candidate, in the opinion of the examiners, has done well in two of these subjects, but has failed in the third, he is allowed to pass in the two and to take the third at another time. The same wise liberality prevails in dealing with the results of the second and final examinations. This liberality, so far from being favoured at the London University, is utterly discountenanced; and if the same want of adaptability to the requirements of different individuals is inaugurated in the proposed new university, it will, I fear, either prove a failure or simply lead to the growth of another Juggernaut like that in Burlington-gardens. This is why I have been watching the movement with anxiety as well as interest. In England we do not worship many things, but there is one thing to which we bow down with the blindest and most unreasoning adoration, and that one thing is the power of examinations to test the ability of candidates to do anything under the sun. I have passed eight examinations, and the only feeling I have now about them is one of deadly hatred, not to the examiners, but to the examinations themselves, feeling as I do that a good deal of the time spent in preparing for them might have been better employed. It is, perhaps, just that the University of London, accepting as it does candidates from all parts of the world, and relying on examination alone to test their fitness for degrees, should make its examinations stringent and inelastic. In a teaching university such stringency would be unnecessary, and the establishment of such a university in London on the liberal principles to which I have referred, although it might be long before it could successfully compete with the well-appointed laboratories and established reputation of the Edinburgh school, would in the end, I have no doubt, achieve a brilliant success. There would still be left to the existing University of London the high function of conferring its degrees on all who might be able to pass its examinations, without any restrictions as to the place where candidates acquired the knowledge that enabled them to do so.

I am, Sir, yours obediently,

WILLIAM J. NOTLEY, M.D., B.A. Lond.

Birmingham, Jan. 1885.

UNSOUND MEAT.

To the Editor of THE LANCET.

SIR,—As a contribution to the discussion in your journal between medical officers of health and veterinary surgeons, I beg to send you a newspaper with report of the case of prosecution for unsound meat, in which I was recently engaged. I may here mention a fact brought out in evidence which the report does not notice. The animal was carried to the shambles in a low cart. The presumption was that it was unable to walk, which was not denied. Notwithstanding the statements of the local veterinary surgeons that the lungs were not diseased, I cut out portions of lung with extensive deposit, which, along with portions of diseased liver, I forwarded to Dr. Littlejohn, medical officer of health, Edinburgh, and to Dr. Russell, medical officer of health, Glasgow. Dr. Littlejohn has since written me that both lungs and liver were extensively diseased, and that both he and his market inspectors had no hesitation in condemning the carcase as unfit for human food. Dr. Russell writes me that he likewise holds the same opinion. He had, however, submitted portions of diseased lung and liver to Mr. McCall, Principal, and Mr. Limont, Lecturer on Anatomy at the Veterinary College, Glasgow, for examination. After microscopic examination they pronounced the disease not tubercular, but lymphadenoma, and considered the flesh fit for human food, Mr. McCall remarking that if it had been tubercular he would have joined Dr. Russell in condemning it. The market inspectors and food inspector coinciding with the opinions of Messrs. McCall and Limont, the carcase, which had been forwarded to Glasgow, was allowed to be sold as wholesome food. In the newspaper report you will see that the local veterinary surgeons all considered the disease tubercular, but affirmed notwithstanding that the flesh was wholesome and fit for human food. I am glad to find such a high veterinary authority as Principal McCall holds a different opinion. Provost Doig, one of the judges, gave a most remarkable reason why he would not condemn the meat, which is not reported in the newspapers. He asserted that the local authority of the county were in the habit of killing animals suffering from pleuro-pneumonia, burying the lungs and other diseased parts, and forwarding the carcases to be sold for human food. If such is the case (and he ought to know as he acted as assessor for the county), the sooner such practices are put a stop to the better.

This case, you will allow, has ended very unsatisfactorily, and might well deter medical officers of health from prosecuting similar cases. For this reason I am anxious that some definite opinion should be formed on the points raised—namely: 1st. Can the flesh of tubercular animals be considered as wholesome food, and allowed to be sold as such in the public markets? 2nd. Can the flesh of an animal suffering from general lymphadenoma be considered fit for human food? With all due deference to the opinions of Principal McCall and Mr. Limont, I cannot convince myself that the flesh of an animal suffering from a constitutional disease, such as lymphadenosis or tuberculosis, can be considered fit for human food, and consumed without danger to the health of persons consuming it. Trusting this communication may be the means of eliciting the opinions of medical men and veterinary surgeons on the questions raised,

I remain, Sir, yours sincerely,

WILLIAM F. MURRAY, M.D., &c.,
Medical Officer of Health to the Town of Forfar.

Forfar, Jan. 4th, 1885.

*** We have no hesitation in saying that the carcase of an animal which had suffered from tuberculosis was unfit for human food, because (1) there is little doubt that the malady comes under the class of specific diseases having for their essential pathology the development of micro-organisms—organisms which during their life processes generate poisons, not improbably of the nature of cadaveric

alkaloids; and (2) animal food-stuffs undergo great deterioration during the progress of the inflammatory state. We cannot speak so confidently with regard to lymphadenosis, as the effect of the growth on the metabolism of the tissues generally is not well understood. At the same time it is better to err on the right side, and in this instance we hold that it would be wise to condemn the meat, considering it is taken from an animal the subject of a general constitutional malady. It seems to us not unlikely that a greater amount of harm is done to public health by the ingestion of diseased meat than either the public or the profession have any idea of.—ED. L.

THE CORONERS' WITNESSES ACT.

To the Editor of THE LANCET.

SIR,—The fact that the profession owes to the late Thomas Wakley, Esq., M.P., the initiation and successful enactment of the Coroners' Witnesses Act induces me to forward you a decision which I have obtained as to the interpretation of the fifth section of the said Act. It has doubtless not escaped your notice that some coroners have laid down the rule that the infirmaries established under the Metropolitan Poor Act, 1867, come under the category of public institutions where, in virtue of the aforesaid fifth section, the medical officers are compelled to make post-mortems and attend to give evidence, under the warrant of the coroner, without fee or reward. I have always protested against this interpretation of the section, and I was confirmed in that view by a conversation I had some thirty years ago with the late Mr. Wakley, who not only gave me his opinion on the subject, but told me all the difficulties he had to encounter from country gentlemen, who thought that a huge expense would be incurred if the surgeons and physicians of our voluntary hospitals were paid fees for post-mortems and for giving evidence in coroners' courts. He further said that it was only because he dreaded that the Bill would be rejected that he assented to the amendment in the fifth section. I on several occasions gave evidence at inquests held by him at the Strand Union Workhouse, and was always paid the customary fees. The infirmary of the workhouse is a building established in connexion with the workhouse, and in no sense can it be regarded as a separate and distinct institution, and therefore prohibiting the payment of the fee in question. By reference to Lumley, the late legal adviser to the Local Government Board, and to a footnote in Glen's "Consolidated Orders," page 179, it will be seen that the central department holds the same opinion on the subject which I have always contended for.

I am, Sir, yours obediently,
JOSEPH ROGERS, Chairman of the Council,
Poor Law Medical Officers' Association.
Montague-place, W.C., Dec. 31st, 1884.

[COPY.]

14, South-square, Gray's-inn, 18th Dec. 1884.

I do not think the fifth section of the Medical Act (Witnesses) applies to workhouse infirmaries. A workhouse infirmary may be described as a building or place belonging to the workhouse, and used for the reception of sick paupers, therefore part and parcel of the workhouse. It would therefore not come under the term of a place attached to a hospital. It is decidedly not a public infirmary or a medical institution, and is not supported by endowments, and undoubtedly not by *voluntary* subscriptions. The question that remains, so if possible to bring it within the section, is, Is a workhouse a charitable institution? There is a case mentioned in Prideaux, vol. ii., 398, and reported in 28 L. J. ex., 326, which is a case where a conveyance was made to trustees to build a workhouse, the contention being that it was a charitable institution, and came within the statute of mortmain; but it was held not to be within that statute, as there were no charitable uses. From that you will gather that an infirmary to a workhouse cannot be, if the workhouse itself is not, a charitable institution; neither can it be a public one for the above reason. Whether it was or not contemplated to include institutions of this sort at the time of the passing of the Act is not of so much importance as whether the infirmary in question comes within the definition of one of those institutions in which the officers are precluded from receiving fees. I am of opinion that such do not come within the fifth section. I should have wished to refer to Lumley's work, but we have not it in the library. The medical officers should sue in the county court.

(Signed) ARTHUR BEETHAM, Barrister-at-Law.

BRITISH GYNÆCOLOGICAL SOCIETY.

To the Editor of THE LANCET.

SIR,—I see that in to-day's LANCET my name is included in the list of elected office-bearers of the British Gynæcological Society. As a matter of fact, I never heard of the existence, or of the proposed existence, of the Society till December 30th, three days after the election, so there is evidently some mistake. On the 30th I received a request from Dr. Heywood Smith to allow myself to be placed on the Council, and on January 2nd I wrote to him declining the offer, for reasons assigned. These reasons implied neither approval nor disapproval of the new Society, a question on which I have no adequate means of forming an opinion.

I am, Sir, yours truly,
King-street, Manchester, Jan. 3rd, 1885. J. THORBURN, M.D.

*** We have received a note from one of the secretaries of the Society correcting the mistake referred to above.—ED. L.

THE EXCISION OF A CEREBRAL TUMOUR.

To the Editor of THE LANCET.

SIR,—It is still, perhaps, open to argument whether the step taken by "F.R.S." in sending to *The Times* an account of the case of excision of a cerebral tumour was, as you have described it, an act displaying more zeal than discretion, or a masterly stroke of policy which might have gone far to settle the vivisection question, had not the patient unfortunately died. "F.R.S." was evidently misinformed by those who instigated his letter (for he has said that he had no personal knowledge of the case), and led to believe that the man's complete recovery was secured when there were still dangers ahead.

The position which you take up with regard to vivisection when you declare that it is morally justifiable and has rendered valuable assistance to medical and surgical science and practice, but requires to be carefully regulated, seems to me sound and unassailable; but it is to be borne in mind that the question is now not between unrestricted and safeguarded vivisection, but between safeguarded vivisection and the total suppression of experiments upon animals. A Society, powerfully patronised and with ample funds at its command, having for its avowed object the final prohibition of all such experiments, keeps up what Miss Cobbe proudly calls a "yearly growing agitation." A Bill with the same aim has been introduced during each of the last two sessions of Parliament, and has obtained considerable support; and those who know something of the temper and tendencies of the enormous additions that are about to be made to the constituencies tell us that they will be readily caught by the clap-trap of the zoophilists, and misled by a pseudo-humanitarian cry which deceives even large numbers of the cultivated classes, if we may judge by the vote at Oxford last year on the grant for Professor Burdon Sanderson's laboratory. An attitude of dignified abstention from controversy on the part of scientific men is all very well, but it is not thus that popular fights are won, and there is no disguising the fact that the question of vivisection will have to be fought out in the popular arena. Under such circumstances silence and contempt are apt to be mistaken for a confession of weakness or conscious guilt, and it would be pusillanimity in those who believe that regulated experiments on animals are essential to the further progress of the healing art to stand aloof from a discussion which, however disagreeable to them, involves such important issues. If men of science are not up and doing, there is a possibility that experiments on animals will be put a stop to within the next ten years by an Act which it might take a quarter of a century of labour and agitation to get repealed.

Are we to leave our future masters to the fallacious guidance of anti-vivisection demagogue and shrieking sisters? or are we to tell them the plain truth in a language "understanded of the people," and teach them how much their own interests are bound up with the progress of

medical and surgical science? That is a question which medical men and scientists ought seriously to consider.

I am, Sir, your obedient servant,

Jan. 6th, 1885. M.D.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE NEWCASTLE EYE INFIRMARY.

As noticed in a previous letter, the foundation stone of this new building was laid only on October 3rd last, but from the fact of the building having been considerably advanced in its basement when this ceremony took place, the hospital is now a long way towards completion, and may be opened in a few weeks. Though devoid of unnecessary luxury and ornamentation, the structure will meet all the necessities of the most advanced views of hospital construction as applied to the special purpose for which it is designed. The buildings will be in the Renaissance style, the materials being red bricks and Dennick stone, with green slates for the roofs. The principal front will be towards St. Mary's-place, an open quiet street, yet convenient to the great north thoroughfare of Northumberland-street. The main entrance will be placed in the centre, and will be distinguished by an open porch with moulded columns supporting arches, above which is designed a projecting oriel window, with balustrade parapet over it. On either side the windows with mullions and transoms will be enriched by stone pilasters with moulded caps and cornices, the whole surmounted by an ashlar parapet and pedimented dormers. The grouping of the whole will be effective and pleasing. The main entrance will divide the ground floor into two parts. That to the east will be utilised as the administrative department, comprising board-room, retiring-room, kitchen, scullery, boiler-house, and the usual offices. The out-patients' entrance and exit are separate and apart from the main entrance, and the apartments to which access is given are so arranged that the patients will take up their positions in the order in which they arrive, proceed to the consulting-room (with dark room attached), and then to the dispensary waiting-room, passing through in the same order and out of the exit door without retracing any part of the route on the upper floors. The wards for in-patients will be provided with nurses' rooms, having windows overlooking the wards. An operating-room and day-room will be also on the upper floor. From the day-room (overlooking the gardens of Laing-place) access is given to the ambulatory for exercise, the roofs over some single-storeyed buildings being used flat for the use of the patients. Nurses' sitting- and bed-rooms will occupy the remainder of the structure. The whole of the buildings will be warmed by the circulation of hot water on the low-pressure system. Ample means of ventilation will be provided on the most approved principles. Messrs. Newcombe and Knowles of this city are the architects, and they would appear to have provided for every necessity of a modern ophthalmic hospital in their arrangement of this building.

THE POLICE SURGEONCY OF NEWCASTLE.

Mr. S. Rayne, who has held for a great many years the office of police surgeon in this city, has resigned through ill health. The post is considered a good one, for, besides having to a certain amount of private practice, there is a salary of £300 per annum attached to it. The vacancy, as may be supposed, has given rise to a considerable amount of activity amongst our junior surgeons here. It has been hinted by some that the office would be divided into districts, and so open out three or more appointments. I believe, however, that the committee will keep the duties very much as they are, and that Mr. J. R. Baumgartner, who has been for a long time associated with Mr. Rayne in police work, will get the appointment.

Newcastle-on-Tyne, Jan. 7th.

SMALL-POX IN NEWINGTON.—At a meeting of the Newington vestry on Wednesday, Dr. Iliff, medical officer of health, reported the existence of a serious outbreak of small-pox in the parish.

EDINBURGH.

(From our own Correspondent.)

THE ROYAL INFIRMARY.

AT a general meeting of the supporters of this institution on the 5th inst. an annual report of a gratifying character was submitted by the managers. During the twelve months with which it dealt, 7624 in-patients (an increase of 795 on the number for the year before) and 2500 out-patients were treated. The ordinary income for the year was £26,796—an increase of £4160 on that for the previous year. The ordinary expenditure showed an increase of £1195. The managers stated that, notwithstanding the depression of trade, which had affected almost every branch of industry in the country, ordinary contributions from all sources showed an increase of £494. From the building fund account, which was also submitted, it appears that the whole cost of the new Royal Infirmary, including the site and furnishing, was £351,826 6*s.* 8*d.* A debt of £50,885 is still due to the bank. The managers are most anxious to have this cleared off, and appeal to the friends of the institution to aid them in accomplishing this end. In moving that the report be remitted to a committee of contributors for examination, the Lord Provost said the document furnished pleasing evidence that the infirmary possessed the confidence of the people of Edinburgh and of Scotland.

THE PRINCIPALSHIP OF EDINBURGH UNIVERSITY.

A meeting of the Curators of the University was held on the 6th inst. in reference to the filling up of the vacancy in the Principalship caused by the death of Sir Alexander Grant, Bart. There were present Lord Balfour of Burleigh, Lord Kinnear, Mr. T. G. Murray, Lord Provost Sir George Harrison, Sir Thomas Jamieson Boyd, Treasurer Boyd, and Mr. Duncan M'Laren. After nearly an hour's deliberation, the meeting was adjourned for a fortnight, without any decision being come to. It is stated that there were before the Curators the names of a number of gentlemen any one of whom would accept the office in the event of its being conferred on him; but that there is really no candidate in the field.

ROYAL COLLEGE OF SURGEONS.

A QUARTERLY MEETING of the Council of the Royal College of Surgeons was held on Thursday, Jan. 8th.

The report of the Committee of Management was agreed to, on Mr. Marshall's motion, as follows:—That members of English Universities who shall have passed in the subjects of the first and second examinations of the scheme, and have completed not less than four years' medical study, be admitted to the final examination of the Board on the payment of five guineas, and be entitled to receive the double licence on payment of twenty-five guineas.

Mr. Hutchinson was elected an Examiner on the Board for Dental Surgery. A petition was received from the Northern Provincial Schools of Medicine urging that arrangements be made for the conduct of written examinations under the scheme at the schools themselves, to avoid the necessity of students coming to town so frequently as would otherwise be needful. This was referred to the Committee of Management for decision.

A communication was received from the Association of Members of the College in reference to the mode of election of members of Council, and was referred to the Committee on Charters and Bye-laws.

A letter was received from the Association of Fellows, containing copies of two resolutions passed at their late meeting. The President was requested to invite the Association to send delegates to the Committee on Charters and Bye-laws to confer with them. The proposal that there should be a general meeting of Fellows and Members was agreed to.

Sir James Paget proposed that the Council take measures for placing in the College some appropriate memorial of the late Sir Erasmus Wilson. This was seconded by Mr. Marshall, and carried unanimously. A motion was passed that it be referred to the President and Vice-Presidents to

consider and report to the Council as to the best way to carry the resolution into effect. It was also agreed that from that date candidates who may have failed in one subject at the primary examination shall be allowed to present themselves in that subject, when eligible to do so, without having to pass again in the subject on which they have satisfied the examiners.

THE SERVICES.

Surgeon-Major W. A. Catherwood and twenty non-commissioned officers and rank and file of the Medical Staff Corps left Aldershot for Egypt on Saturday.

MILITIA MEDICAL STAFF. Surgeon-Major E. Thompson David Harrison, 4th Battalion, the South Wales Borderers, resigns his commission; also is permitted to retain his rank and to wear the prescribed uniform on his retirement.

YEOMANRY CAVALRY.—Royal 1st Devon: Surgeon Albert de Winter Baker resigns his commission.—Leicestershire: John Thomas Jacques, Gent., to be Surgeon.

ADMIRALTY.—The following appointments have been made:—Surgeon Charles William Sharples, to the *Falcon:* Fleet Surgeon George Maclean, M.A., M.B., to Haslar Hospital; Fleet Surgeon James Flanagan, to the *Northumberland;* Staff Surgeon Robert W. Williams, to the *Briton.*

RIFLE VOLUNTEER CORPS.—2nd Volunteer Battalion, the Queen's Own (Royal West Kent Regiment): Honorary Assistant-Surgeon Flaxman Spurrell resigns his commission.—2nd (South) Middlesex: Acting Surgeon Francis Alexander Stokes resigns his appointment.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 1st inst.:—

Ensor, Henry Collen, Guy's Hospital.
Hart-Smith, Franke Chamberlain, University College.
Michell, John Charles, London Hospital.
Thurston, Daniel, London Hospital.
Watt, Alex, Kinnear, Edinburgh University.
Wethered, Frank Joseph, London Hospital.

The following gentleman also on the same day passed the Primary Professional Examination:—

Richard Henry Botham, King's College.

MR. H. BAYS has contributed £1000 as a New-Year's gift to the Walsall Cottage Hospital.

THE HUNTERIAN ORATION.—The Biennial Oration in memory of John Hunter will be delivered in the theatre of the Royal College of Surgeons on Saturday, the 14th prox., by Mr. John Marshall, F.R.S.

CHARING-CROSS HOSPITAL MEDICAL SOCIETY.—There will be a meeting of the Society on Friday, the 16th inst., at 8 o'clock, when a paper will be read by Mr. Rorrie Fletcher on "Fracture of the Patella."

PRESENTATION.—On the 24th ult., Dr. Daniel Richmond, of Paisley, was presented with a portrait of himself and a cheque for £463, in commemoration of his having attained his jubilee as a medical practitioner.

LOCAL HEALTH OFFICERS in the State of New York are hereafter to be appointed only after a competitive examination, in accordance with the new Civil Service rules. The examination papers are to be prepared by an examining board of five physicians, to be designated by the Civil Service Commission, and the examinations are to be held in the presence of a county judge, who will transmit the papers to the Commission.—*New York Medical Journal.*

ROYAL INSTITUTION.—Professor H. N. Moseley will on Tuesday next, Jan. 13th, begin a course of five lectures on "Colonial Animals, their Structure and Life Histories." Professor Dewar will on Thursday, January 15th, begin a course of eleven lectures on "The New Chemistry"; and Dr. Waldstein will on Saturday, January 17th, begin a course of three lectures on "Greek Sculpture, from Pheidias to the Roman Era." The Friday evening meetings will begin on January 16th, when Professor Tyndall will give a discourse on "Living Contagia."

DR. W. H. O. SANKEY has been elected Membre Associé Étranger of the Medico-Psychological Society of Paris.

COLLEGIATE PRIZES.—The members of the Royal College of Surgeons, and indeed the profession generally, will be surprised to hear that no essays have been sent in for the Jacksonian Prize for such an interesting subject as the "Surgical Treatment of Uterine Tumours, both Innocent and Malignant." The subject for this prize for the present year is the "Diagnosis and Treatment of such Affections of the Kidney as are amenable to Direct Surgical Interference." The essays must be delivered on or before Thursday, the 31st December next.

THE EPIDEMIC AT KIDDERMINSTER.—The 4th inst., the first Sunday in the New Year, was observed as a day of special thanksgiving in the churches and chapels of Kidderminster for the abatement of the typhoid fever epidemic, which broke out in August and has not yet entirely disappeared. The mayor and corporation officially recognised the occasion as an exceptional one, and attended in state the services at the parish church. Collections were made for the relief of the convalescents, of whom several hundreds have been sent to convalescent homes.

A MEETING of the Watford Local Board was held recently to take into consideration the serious outbreak of diphtheria in the town. The medical officer pointed to the sewer gratings as the primary cause, and the surveyor stated that, though he was constantly flushing and using disinfectants to the open sewers, he could not abate the offensive smells arising from them. A majority of the board were in favour of closing the ventilators and erecting chimney shafts, but at the suggestion of the chairman the surveyor was instructed to bring up a report without delay.

METROPOLITAN DAIRYMEN'S BENEVOLENT INSTITUTION.—The tenth anniversary dinner in aid of the funds of this large and important charity was held on Thursday, Dec. 11th, at the Freemasons' Tavern, Great Queen-street. E. C. Tisdall, Esq., of Holland Park and Esher, one of the founders, was in the chair. He was supported by about 350 representative members and visitors. In his speech he mentioned the fact, most interesting to us, that "the men who have been fined in this institution of above 1000 members can be counted on the fingers of one hand." The stewards' returns showed a sum of £756 10*s.* 6*d.*

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ARMSTRONG, JAMES, M.B.Ed., L.R.C.S.Ed., has been appointed a Hon. Medical Officer to the Liverpool Ladies' Charity and Lying-in Hospital.

BARNARD, ARTHUR J., M.R.C.S., L.R.C.P.Ed., has been appointed Junior House-Surgeon to the Darlington Hospital, vice Louis Robinson.

BOWHAY, ALBERT, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer and Public Vaccinator to the Beerferris District of the Tavistock Union, vice H. J. S. Liddell.

BRIGGS, HENRY, M.B., F.R.C.S.Eng., has been appointed Honorary Medical Officer to the Ladies' Charity and Lying-in Hospital, Liverpool.

BROATCH, GEORGE T., M.B., C.M., has been appointed Assistant Medical Officer to the East Riding Asylum, vice A. C. Suffern, M.D., resigned.

BROWNE, ARTHUR E. NEWBURY, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Third District of the Pewsey Union, vice Fulcher, resigned.

CLARKE, ERNEST, B.S.Lond., has been appointed Surgeon to the Miller Memorial Hospital.

CLEMOW, ARTHUR H. W., M.B., C.M.Ed., has been appointed Senior Resident Medical Officer to the Royal Free Hospital, Gray's-inn-road, vice Dr. Rabbeth, deceased.

CREED, THOMAS, M.D., has been appointed Medical Officer to the Miller Memorial Hospital.

CROCKER, J. HEDLEY, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Eccles and District Medical Association, Hampden-grove, Patricroft, near Manchester.

DUNN, H. PERCY, F.R.C.S., has been appointed Assistant Ophthalmic Surgeon to the West London Hospital.

FENNER, ROBERT, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the North Repps District of the Erpingham Union, vice Fluder, deceased.

HARTT, CHARLES H., L.R.C.S.I., L.K.Q.C.P.I., L.M., Medical Officer of Health for Greenwich, has been appointed Medical Officer to the Miller Memorial Hospital, Greenwich.

JOHNSON, THOS. RUSSELL, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the North-East District of the Patrington Union, vice Raines, deceased.

KING, FRANCIS J. F., M.B., B.Ch. Univ. Dub., has been appointed Resident Medical Officer to the Monkstown Hospital, co. Dublin.

MOORE, THOMAS, F.R.C.S., has been appointed Surgeon to the Miller Memorial Hospital.

MOTON, HENRY JAMES, L.D.S. R.C.S.E., has been appointed Dental Surgeon to the North Surrey District Schools, Anerley.

NASH, H. CHESTER, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond. (late Resident Medical Officer to the Children's Hospital, Pendlebury, Manchester), has been appointed House-Surgeon to the Norfolk and Norwich Hospital, Norwich, vice D. D. Day, M.B., F.R.C.S., resigned.

POLAND, JOHN, F.R.C.S., has been appointed Surgeon to the Miller Memorial Hospital.

SHILLOW, FRANCIS McDONALD, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Silkstone District of the Penistone Union, vice McCoubrey.

THOMAS, WILLIAM, M.B., B.S., B.Sc.Lond., has been appointed House-Surgeon to the Clinical Hospital, Manchester.

WILLIS, WILLIAM, L.R.C.P.Ed., has been appointed Medical Officer to the Miller Memorial Hospital.

WORTHINGTON, THOMAS B., B.A., M.D. Trin. Coll. Dub., Senior Assistant Medical Officer at the Sussex County Asylum, Hayward's-heath, has been appointed Medical Superintendent to the Hants County Asylum, Knowle Fareham, vice Dr. Manley, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BENHAM.—On the 6th inst., at Museum-street, Ipswich, the wife of Henry James Benham, M.D.Lond., of a daughter.

BURNHAM.—On the 27th November, at 157, Simcoe-street, Toronto, the wife of Dr. Herbert Burnham, of a daughter.

CHANT.—On the 1st inst., Mrs. Ormiston Chant, wife of Thos. Chant, M.R.C.S., of a daughter.

GRANGER.—On the 27th ult., at Nicholas-street, Chester, the wife of Farington Marsden Granger, M.R.C.S., of a son.

HUTCHESON.—On the 4th November, at Allahabad, the wife of Surgeon-Major G. Hutcheson, M.D., of a son.

PATERSON.—On the 1st inst., at Amatola, Great Western-road, Aberdeen, the wife of A. Gordon Paterson, M.B., C.M., of a daughter.

SAUL.—On the 5th inst., at Fenton-Cawthorne House, Lancaster, the wife of Dr. Wingate Saul, of a daughter.

STEPHEN.—On the 2nd inst., at Queen's-gate-terrace, S.W., the wife of Andrew Stephen, M.D., of a daughter.

MARRIAGES.

FERGUSON—BUTTERWORTH.—On the 19th November, at St. Paul's Church, Dunedin, H. Lindo Ferguson, M.A. Trin. Coll. Dub., F.R.C.S.I., third son of the late William Ferguson, of Dublin, to Mary Emmeline, eldest daughter of J. Leech Butterworth, Esq., of Dunedin, Otago, New Zealand.

HENDERSON—BULL.—On the 6th inst., at St. Michael's Church, Highgate, by the Rev. Edgar Smith, Vicar of All Saints, Highgate, assisted by the Rev. D. Trinder, Vicar of St. Michael's, Alexander Mair Henderson, M.D., son of George Henderson, of Whitebrook, Keith, N.B., to Florence, eldest daughter of Henry Bull, of Ravensmount, Hornsey-lane, N.

TREVOR—WILLIAMS.—On the 31st ult., at St. Augustine's, Kilburn, Edward Tull Trevor, M.R.C.S., L.R.C.P.Lond., of Great Yarmouth, to Martha Margaret, only daughter of John Williams, late of Upper Westbourne-terrace.

WALLER—PALMER.—On the 6th inst., at the Friends' Meeting House, Reading, Augustus D. Waller, M.D., son of the late Augustus Waller, M.D., F.R.S., to Alice Mary, second daughter of George Palmer, Esq., M.P.

WELDON—CREED.—On the 31st ult., at Holy Trinity Church, Kensington, George Weldon, M.D. Caius Coll. Camb., to Beatrice Mary, daughter of the late Colonel Henry Creed, Royal Horse Artillery, late of Bucknalls, Hertfordshire.

DEATHS.

BOURCHIER.—On the 22nd ult., after a long illness, John Dunbar Bourchier, L.R.C.P., L.R.C.S.I., L.S.A.Lond., of Hopton-road, Tooting-park, Streatham, aged 36.

CLOUGH.—On the 12th November, at Gympie, Queensland, Australia, Major Edmund Clough, M.R.C.S., L.R.C.P.Ed., L.M., late of Bingham, Notts, and Hambledon, Hants, aged 28.

DAVIES.—On the 4th inst., at his residence, Vale Mount, Hampstead, Robert Davies, M.D., F.R.C.P., of Finsbury-square, aged 66.

GODFRAY.—On the 5th inst., at his residence, 81, New-street, Jersey, Charles Amiraux Godfray, M.R.C.S., in his 34th year. Friends will kindly accept this intimation.

HAO.—On the 4th inst., suddenly, William Banks Hao, M.R.C.S.&L., M.D. Aberdeen, L.R.C.P.Ed., of 1, Albion-street, Hull, aged 68.

MAYNARD.—On the 1st inst., at Hastings, Forster F. M. Maynard, L.R.C.P.Lond., M.R.C.S.Eng., eldest son of the late Rev. Forster-Maynard, Rector of Kirk Bramwith, Yorkshire.

MORTON.—On the 28th ult., at his residence, The Coëd, Stroud, Gloucestershire, George Edward Morton, M.D., Inspector-General, H.M. Indian Medical Service (retired).

SANDILAND.—On the 4th inst., suddenly, of spasmodic croup, Denys, youngest son of A. H. Sandiland, L.R.C.P.Lond., of Oakley House, Camden-road, N.

STOKES.—On the 1st inst., at his residence, Howell-road, Exeter, Henry Stokes, M.D.

STUART.—On the 14th ult., at 4, Kyd-street, Calcutta, Dr. Kenneth Bruce Stuart, aged 49.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, January 12.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

MEDICAL SOCIETY OF LONDON.—Dr. Heron will show Specimens in Pure Cultivation of the Comma Bacillus.—Dr. Samuel West: A Case of Aphasia; Lesion in the Supra-marginal and Angular Gyrus.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Election of Officers and Council.—Communication from Mr. E. A. Bogue of New York.—Mr. Storer Bennett: "Herbst's Method of Filling Teeth with Gold."—Valedictory Address by the President.

Tuesday, January 13.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., and on Fridays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Adjourned discussion on Dr. Kidd's paper on the Distribution of the Tubercle Bacilli in the Lesions of Phthisis. Dr. Kidd's Specimens will be on view half an hour before the meeting.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Mr. Oldfield Thomas: Account of a Collection of Human Skulls from Jervis Island; Torres Strait.—Mr. A. L. P. Cameron: Notes on some Tribes of New South Wales.

ROYAL INSTITUTION.—3 P.M. Prof. Moseley: Colonial Animals.

Wednesday, January 14.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour. Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

HUNTERIAN SOCIETY.—7.15 P.M. Council.—8 P.M. Dr. Radcliffe Crocker: The Internal Administration of Turpentine in Cutaneous Diseases.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—7.30 P.M. Meeting of Council.—8 P.M. Surgeon-General W. J. Moore: The Constitutional Requirements for Tropical Life, with especial reference to Temperaments.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. A. D. Michael: Notes on the Life History of some of the little known Tyroglyphidæ.—Mr. C. Thomas: On a New Species of Acineta.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Edis, Mr. W. S. A. Griffith, Dr. Amand Routh, Dr. Heywood Smith, and others.—Dr. William A. Duncan: On the Extirpation of the Entire Uterus.

Thursday, January 15.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—8 P.M. Prof. Dewar: The New Chemistry.

Friday, January 16.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—9 P.M. Prof. Tyndall: Living Contagia.

Saturday, January 17.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Dr. Waldstein: Greek Sculpture.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

INFLUENCE OF THE WEATHER UPON NERVOUS SUFFERERS.

DR. EYSELEIN of Blankenburg has called attention to the fact that nervous sufferers are unfavourably affected by the presence of a large proportion of ozone in the air. At the same time he remarks that a moderate proportion is undoubtedly beneficial. Referring to barometrical variations, he attributes to heavy air a tranquillising influence upon persons who are suffering from nervous disorders.

Mr. F. D. Askey.—Our correspondent's argument is based on the assumption that *vaccinia* and *variola* are one and the same disease. This—the original opinion of Jenner—has no substantial support in experience. It is generally accepted that vaccinia does not obey the same laws in its propagation as those which obtain with regard to variola. Vaccinia can only be communicated by direct transference or inoculation; it is not infectious like variola.

Mr. Woodson.—We regret we cannot assist our correspondent in his object.

FOUR TWIN BIRTHS IN SUCCESSION.

To the Editor of THE LANCET.

SIR,—On the evening of Dec. 17th I delivered Mrs. O——, aged twenty-nine years, the wife of a small farmer living about two miles from my house, of twins. In conversation I found that this was the fourth time in succession that she had been delivered of twins. She was born on Sept. 15th, 1855, was married on June 1st, 1871 (at the age of sixteen years), and had been delivered in order of the following:—1872, July 27th, girl; 1874, March 11th, boy; 1876, Jan. 18th, boy; 1877, Oct. 7th, girl; 1880, Aug. 24th, twins, boys; 1881, March 12th, twins (fourth month) boys; 1883, April 6th, twins, boy and girl; 1884, Dec. 17th, twins, girls. All the children, with the exception of the one born in 1874 (who died in convulsions in 1876) and the children delivered in 1881, are living and healthy. There was in each case of twins but one placenta. I may add that the left hand of the first child born in December last is absent, the ends of the radius and ulna apparently having no covering but connective tissue and skin. The mother of Mrs. O—— had twins upon two occasions, with two single pregnancies between. I can find no recorded case of four consecutive twin pregnancies. This case may therefore interest your readers.

I am, Sir, yours faithfully,

Hinton, Salop, Dec. 27th, 1884. JOHN HANNAY.

"A NEW DISEASE."

THE Russian doctor who has invented "Psychopathy" is to be congratulated on his ingenuity and fertility of resource rather than on his scientific acumen. The mental craze and moral hebetude included under this new term is a perfectly well-recognised form of what Dr. Prichard classed as "moral insanity." No creation of a special term was necessary.

Leeds.—The card is in bad form, and especially the distribution of it. It is advertising, and should be discontinued by consultants. The profession of the neighbourhood should collectively express its disapproval.

Mr. Roger T. Smith.—Inquiry shall be made into the matter.

THE BOATS BETWEEN CALAIS AND DOVER.

To the Editor of THE LANCET.

SIR,—I beg to call attention to the lack of protection afforded from weather in the boats which run between this country and the Continent. Surely, in the present inclement season it behoves the companies to see to this important matter, which should easily and promptly be remedied. Trusting your lay contemporaries will echo this idea, and bring pressure to bear in the right quarter, I am, Sir, yours truly,

London, Dec. 20th, 1884. JOHN LUCAS, M.D., F.R.C.S., &c.

WHITTLE AND HUTCHINSON FUND.

THE following additional contributions have either been received or promised:—

Dr. J. Cameron	...	£10	10	0	Mr. F. W. Lowndes	...	£1 1 0

Subscriptions should be sent to Dr. Nevins, 3, Abercromby-square, Liverpool, or to the "Whittle and Hutchinson Fund," North and South Wales Bank, Hardman-street, Liverpool.

Mr. H. W. Smith.—Certainly not. There is no monopoly of knowledge in medicines nowadays.

WE agree with a correspondent, that advertising the names of physicians and surgeons of hospitals in newspapers is objectionable.

SMALL-POX BREAKING OUT AFTER FULL DEVELOPMENT OF VACCINATION.

To the Editor of THE LANCET.

SIR,—Out of a large number of small-pox cases I have attended in this neighbourhood the following is one of some interest, as showing how vaccination ran its regular course in a patient whose system must have already been infected with small-pox poison, and where also the small-pox was uninfluenced in any way by the vaccination.

Emily W——, aged twenty-one, on Dec. 23rd had primary vaccination performed. In a day or so she began to complain of her arm. On the 27th she was obliged to take to her bed with a bad headache and severe lumbar pain and tenderness. On the 30th the vaccination had taken well in four places; there was no swelling or inflammation of the arm; the lumbar pain and tenderness had increased. On the 31st the pain was slightly better, but the back was still very tender; the patient vomited twice during the morning, was very feverish, and would take no food; two small vesicular spots appeared near the mouth. On Jan. 1st the pain and tenderness of back were much better, and the patient was covered with a typical small-pox rash; towards evening she became delirious, and had a very bad night; she has since been removed to a hospital. The patient's sister (who had been sleeping with her up to the day before the rash made its appearance) was revaccinated on the same day (Dec. 23rd), and took well, as did others who were vaccinated with matter from the same source. I am, Sir, yours truly,

Lower Norwood, Jan. 6th, 1885. CHAS. E. ADAMS, M.R.C.S., L.S.A.

M. M. M.—If the contents of the cesspool are still liquid, a strong solution of common sulphate of iron, made by adding the salt to ten times its weight of hot water, should be abundantly applied before removal. Failing this, use a solution of chloride of lime. If it is desired to keep the contents as dry as possible, recently burnt lime may be thrown in. The liquid contents, on removal, should be at once applied to land and dug in; any heap of filth being covered with freshly burnt lime or clean dry earth.

G. H. S.—The best course is to bring pressure to bear upon the Beckenham Local Board of Health to provide a small hospital for the isolation of first attacks of infectious diseases occurring in their district. They have full power to do this under Section 131 of the Public Health Act 1875. Communication of the details to the Local Government Board might be helpful.

THE CHOLERA EPIDEMIC IN EDINBURGH IN 1848–49.

To the Editor of THE LANCET.

SIR,—Could you or any of your readers inform me where I shall find a record of the epidemic of Asiatic cholera as it visited Edinburgh during 1848–49. I am, Sir, yours truly,

Devonport, Dec. 10th, 1884. EVERARD HOME SAUNDERS, Surgeon, Royal Navy.

*** We are unable to find any connected account of cholera in Edinburgh in 1848–49; even the Scotch medical papers of that date fail to supply any adequate information. Under the heading of "Cholera," however notices will be found in the *Monthly Journal of Medical Science* vol. 1848–49; the mortality statistics could also be procured; and so general idea of the epidemic could be made out.—ED. L.

THE DOCTOR'S WIFE.

A SOMEWHAT interesting legal action is reported in a recent number of the *Glasgow Herald*, in which a widow lady tried in the sheriff's court to recover £50 in respect of injuries to her health from a medical man, which injuries were alleged to have been produced by medicines prescribed and supplied in the absence of the medical man by his wife. It was sought to show that in this case the wife was the agent of her husband, and that he was responsible. The injuries alleged were salivation and its consequences, due to a quantity of mercury prescribed by the defender's wife. The defender denied that the powder given contained anything unusual either in quantity or quality, and, while admitting that his wife occasionally assisted "in the shop" in his absence or that of the assistant, denied that his wife had any authority to prescribe. He argued that the pursuer (plaintiff) took the risk of the suitability of the powder. Sheriff Guthrie, in giving judgment in accordance with this view of the case, dismissed the action, and found the pursuer liable in expenses. Most people will agree with this judgment. It would be absurd to think that any sane person could conclude that a doctor could delegate prescribing powers to his wife. At the same time the case may serve as a useful warning to good wives, who abound in the medical profession, in the absence or agency of their husbands to be, if not "wise as serpents," at least "as harmless as doves."

"AGORAPHOBIA."

To the Editor of THE LANCET.

SIR,—I was interested in reading Dr. White's account of his case of "agoraphobia" in your columns. I have for years been subject to the complaint. My first symptoms came on about nine years ago, with a loss of confidence in myself in dispensing; this lasted for some time, then was followed by a period of religious mania for a few weeks. I sold my practice, and the latter symptom gradually went off; then came on the "agoraphobia"; and I have been for years more or less, according to symptoms, frightened to go any greater or lesser distance from home, lest I should be taken ill away from aid; sometimes even the presence of a companion not being sufficient to calm my fear. Other symptoms have been a throbbing of the carotids, I suppose on lying down in bed, and I have awoke sometimes with numbness in the right arm or hand if I lay on that side. My worst symptom now is the "agoraphobia," and that perhaps when I have done a thing I may go back again and again before I can rest assured I have done it or done it right. I attribute my illness to excitement, worry, and over-work; but, as there is nothing now in my surroundings to retard my recovery, I should be glad if any kind correspondent would give an account of a case he has treated satisfactorily.

I am, Sir, yours truly,

Jan. 6th, 1885. SURGEON.

"STREET ILLNESS AND BAD POLICE AND WORKHOUSE REGULATIONS."

To the Editor of THE LANCET.

SIR,—The extract from *The Times* which you quote in your last issue reflects unfavourably upon the authorities at this institution. The facts are these:—A constable, at half-past six on the morning of the 22nd ult., drove up in a cab, and applied to the porter at the workhouse, saying that a man was all in the vehicle, but failed to state that he deemed it an urgent case. The porter on duty did not therefore refer to either of the medical officers of the infirmary, but acted, in the apparent absence of urgency, as he is instructed to do by the guardians, in sending the case to the divisional surgeon of police, who is within two minutes' drive of the workhouse.

I need hardly add that all cases of severe and sudden illness are at once admitted, irrespective of the social position and parish to which the person belongs, if harm might accrue from the delay in obtaining the usual order; and in this case, had the attention of the resident medical officer been called to the condition of the patient, he would undoubtedly have been admitted.—Yours obediently,

H. P. POTTER,

Kensington Infirmary, Jan. 5th, 1885. Medical Superintendent.

THE MEDICAL DIRECTORY FOR 1885 AND THE NORTH-WEST LONDON HOSPITAL.

To the Editor of THE LANCET.

SIR,—In the Medical Directory for 1885 the names of Sir Andrew Clark and Mr. Christopher Heath are given as members of the consulting staff of the North-West London Hospital. As these gentlemen have ceased to continue their connexion with this institution, as shown by a copy of a letter herewith enclosed, I feel it my duty to call public attention to the error committed by those who are responsible for such erroneous information being communicated to the Directory.

I am, Sir, your obedient servant,

A GOVERNOR OF THE NORTH-WEST LONDON HOSPITAL.

Dec. 30th, 1884.

"16, Cavendish-square, Nov. 18th, 1884.

"DEAR DR. CULLIMORE,—I deem it my duty to inform you, as chairman of last night's meeting, that Mr. Heath and I, after fully considering the matter, have resolved to terminate our connexion with the North-West London Hospital. Perhaps you will kindly communicate the substance of this note to the other members of the meeting.

"Faithfully yours,

"ANDREW CLARK."

THE PRACTICE OF MEDICINE IN RUSSIA.

THE number of medical men in Russia, according to the official statistics for 1883, is 15,231, the majority being residents of cities, and the country very badly supplied. There are medical faculties in Kief, Kazan, Charkov, Moscow, Warsaw, Helsingfors, and Dorpat, the first five of which give instruction in the Russian language, while at Helsingfors Swedish is spoken, and at Dorpat German. There is, besides, an army medical school. In the Russian schools there is a five years' graded course, with yearly examinations. At the end of this course an examination must be passed for the title of physician, after which, if it is so desired, the candidate may pass on to the doctorate examination, in order to obtain which degree a more exact knowledge of theoretical subjects is necessary than that required at the examination for the title of physician. A doctor ranks as eighth in the classes defined by the State, while a physician is one step farther down the scale. Russia has a paternal Government, and her medical sons are not neglected, but are placed under the care of the Minister of the Interior. The business of the Minister of the Interior is defined to be to watch "the industry and scientific ability of the physicians, and to report thereon yearly." The Government also takes them under its protection when they are subject to unjust attacks. Regarding fees, too, a law for their regulation passed in 1789 still remains on the Statute Book; but owing to the extreme smallness of the fees allowed, it is practically a dead letter, although, of course, it can be enforced at any time. Russian medical societies are not very flourishing, owing to an every-man-for-himself spirit that exists among the physicians there. The oldest is the Society of Russian Physicians, founded in 1833. The members of this society are intensely national in their feelings, as was evidenced in one of the addresses at their semi-centennial celebration, when the speaker congratulated his hearers that at last Russian medicine had thrown off the German yoke. This feeling was also exhibited in an order recently promulgated by the Minister of War, to the effect that not more than 4 per cent. of the army surgeons should be Jews. There are five other societies, one of them composed chiefly of German physicians, in St. Petersburg, and seventy-three in the provinces. In addition there are several mutual aid and benefit societies among medical men. Considerable progress has been made in the last decade in medical journalism. The leading journal is the *Vratch*, founded by Manassein in 1880. Next to the *Vratch* comes the *Russkaya Medicina* and the *Meditsinski Vestnik*. Another journal, composed principally of abstracts, but containing also some original articles, is the *Meditsinskoye Obosrenoye*. The organ of the German physicians is the *St. Petersberger Medicinische Wochenschrift*.

Beta.—The undertaking is an unreasonable one. But a contract is a contract, and must be regarded.

"THE P. AND O. COMPANY'S MEDICAL SERVICE."

To the Editor of THE LANCET.

SIR,—I write to you as a private practitioner who is in the habit of advising a sea voyage to many of his patients as a means of cure, to ask you by your powerful aid to encourage the medical officers of the P. and O. Company to one and all refuse to submit to the extraordinary circular published by your correspondent, "A P. and O. Surgeon," in to-day's issue of THE LANCET. Should the circular be persisted in, I cannot think that any self-respecting medical man will remain a day longer than he is compelled in the service of a company that would simply force him to act as a dispenser of nostrums which, although perhaps not immediately dangerous to life, would very often inflict great injury upon the persons for whose health he ought to be held responsible. It has been my habit when sending a patient a voyage, if he required a continuance of treatment, to always communicate privately with the ship's surgeon, and indicate the course of treatment my patient was undergoing, and to ask him kindly to give the passenger named the benefit of his advice, should it be necessary. Now, if this ill-judged circular is persisted in, I shall feel that the P. and O. line is shut to my patients, if I do not want them to become confirmed opium eaters, or the victims of chloral, or mercurial, or arsenical poisoning, from their being able to extort from their doctor at sea prescriptions that I should never have permitted them to handle on shore.—Yours truly,

Jan. 3rd, 1885. M.R.C.S.Eng.

DISCUSSION OF MEDICAL QUESTIONS IN THE LAY PRESS.

A CORRESPONDENT complains of this practice by what he calls the "Birmingham celebrities." We wish they were the only sinners in this respect. But the subject is too serious to be discussed here.

H.—The case is not quite a simple one. The friends naturally felt anxious, and wanted an independent, separate opinion. They erred in not being more frank with Dr. H——. Mr. E—— should have told them—perhaps he did tell them—to inform Dr. H——.

Subscriber.—There is nothing in the qualification to legalise the use of such a title.

Dr. F. J. Mouat.—Next week.

WILD ANIMALS AND SNAKES IN INDIA.

THE loss of life from wild animals and snakes in India was greater both in human beings and cattle during 1883 than in the previous year. The increase is not very large, but it has for several years past been continuous, and the deaths during 1883 amounted to 22,905. Of this number 20,067 are put down to snake-bite.

Mr. Stephens.—Our correspondent has clearly a claim against the guardians, not having received any instructions from them not to accept the relieving officer's orders for midwifery cases. The guardians are answerable for the errors of their servant, and it is their place to get from him the fees which are due to the medical officer.

J. R.—The statement is not clear enough for us to express a judicial opinion on the case.

A REMEDY FOR STREET NOISES.

To the Editor of THE LANCET.

SIR,—Some years ago, owing to illness and long residence in the tropics, I became morbidly sensitive to noises of every kind, and procured complete relief in the following way. I placed some spermaceti ointment in the centre of a little square of thin, limp cotton, brought the corners together, tied them with thread, and inserted one of the little plugs well into each ear, and after a little kneading and gentle pressure found that I was absolutely deaf to all ordinary noises, such as the loud barking of dogs and the rumbling of heavy carriages in the streets. A couple of points must be carefully attended to. The ointment must not be too soft, the quantity about the size of a small pea, and the little bag must be somewhat larger than its contents, to allow the plug to take the shape of the auditory canal. If the bag be too small, or its contents larger in size than a pea, it cannot be inserted into the ear, and if applied only to the orifice it entirely fails in its object. This little experiment is easily tried, and a daily experience of over twelve months warrants me in saying that it will be found invaluable in the sick room. I am, Sir, your obedient servant,

London, Jan. 4th, 1885. M.D.

Ultra.—The Registrar-General's Annual Reports are published by Messrs. Eyre and Spottiswoode, Queen's Printers, East Harding-street, Fetter-lane, and may be ordered through any bookseller. The price of the last published Annual Report, relating to the year 1882, is 2*s*.

THE TITLES OF AN APOTHECARY.

L. S. A. is scarcely likely to be molested for calling himself surgeon-accoucheur. But we must admit that such titles are not covered by the qualification which confers upon its owner the title of apothecary.

Vaux.—The degree in question is not equal to a British one, but is fairly respectable. It carries the title of M.D. It is not registrable in England, and the collapse of legislation suggests no prospect of its becoming so.

Clinical Lectures
ON
CASES ILLUSTRATING RENAL SURGERY.

Delivered at University College Hospital,

BY ARTHUR E. BARKER, F.R.C.S.,
ASSISTANT PROFESSOR OF CLINICAL SURGERY AT UNIVERSITY COLLEGE, AND ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE I.

CASE 1.—*Excision of the Kidney for Ruptured Ureter and Urinary Abscess, in a Child aged three years and eight months; Recovery.*

GENTLEMEN,—Several cases illustrating points of interest in renal surgery have lately come under my care, which I have thought might be profitably brought to your notice in the form of a clinical lecture. I have been reminded of these quite recently by a case in which, as you will remember, I removed the right kidney from a child three weeks ago—a case almost unique in itself, and not only very instructive from the facts observed in connexion with its clinical features, but also suggestive of many points to be observed in the future, both clinical and physiological. It is proposed now to bring this case under your notice somewhat in detail, and then, if time permit, to give a sketch of three other cases in which I also operated on the kidney, drawing whatever lessons may be learned from each. The notes of these latter have been written and lying by me for some months past, and I shall have little more to do than read them in abstract and make a few brief comments.

The first case is that of a child, A. W——, aged three years and eight months, who was run over by a hansom cab on Aug. 13th, 1884, at 2.45 P.M., and was immediately brought to the hospital. When admitted the notes state that there was extreme bruising of the left side, and the mark of a wheel having passed across as far as the anterior iliac spine. The right side is no doubt meant, for when I saw the case next day the wheel-mark was plainly on the right, as were all other evidences of mischief. There was also tenderness over the kidney. There was no loss of power or pain in the lower limbs. The abdomen, however, was very tender all over and somewhat swollen. Beyond these there were no points to note about the patient, who suffered but little from shock. The next day he was as before; and it is noted that he had passed water naturally, but that it contained two or three small blood-clots; he had also been very sick during the night. At this time I saw him, and, finding no distinct evidence of any internal injury, directed him to be kept perfectly quiet, with hot fomentations over the abdomen, and that there should be no manual examination of the latter lest some disturbance of possible healing processes might take place, and as nothing could be gained by further examination. On the 19th it is noted that the abdomen continued painful, that there was distinct resistance in the abdominal wall over the right flank and iliac fossa, with dulness over the same area, and pain on pressure. Two days later these symptoms were less marked, and it appeared as though they were due to some effusion of blood in the abdominal wall rather than anything deeper down. The bowels were moved naturally, and the temperature, which had risen at first on two or three occasions above 102°, was now about normal all day. For the next few days there was nothing to note about the child's general state, and he left the hospital to go home on Aug. 28th. It may be mentioned here, however, that the boy appeared rather a delicate child. He had had bronchitis several times, and enlarged glands on the right side of the neck since a year old. He had a congenital scrotal hernia on the right side. His parents, however, are healthy, and there is no family history of phthisis.

So far you will observe, gentlemen, that the question of any serious abdominal lesion appears to have been negatived. Had the liver, intestines, bladder, or spleen been injured, there would probably have been severe shock; rupture to the liver would also probably have led to effusion of blood into the peritoneum, and the same may be said of the spleen, but there was no effusion during the fifteen days the patient was in hospital on the first occasion. Again, the bowels acted normally all this time, showing that the intestines were intact. The urine, too, was passed naturally, indicating that the bladder had escaped injury. The only symptom pointing to any lesion of note was the passage of two or three small worm-like blood-clots in the urine first voided. No other urinary symptom was present; but this, nevertheless, was a most valuable piece of evidence, as was proved subsequently. You will please note also that after the first few days the temperature fell to normal, and there was no evidence of any inflammatory trouble anywhere. But on returning home on May 28th the patient's condition appeared to grow worse. He seemed restless and in pain, and he was brought back to us two days later. On his readmission, on Sept. 1st, I examined him carefully, and found a fluctuating swelling filling the right side of the abdomen. This tumour had all the characteristics of a hydronephrosis or of an accumulation of urine in the flank, to which I will beg you now to give attention. The tumour reached from the right twelfth rib to the iliac fossa, where it was rounded off with a well-defined margin, and filled up the whole flank as far as the middle line to the level of the umbilicus. There was distinct fluctuation over all this region, and dulness on percussion from the loin forwards until the anterior and inner aspect of the swelling was revealed, where it was bounded by the colon. The patient could lie in any position and could extend both thighs equally; there was no heat, redness, or swelling of the skin, and the temperature was normal. From all these facts, coupled with the history of the injury, and the passage of two small worm-like clots in the first urine voided after the accident, I came to the conclusion that the case before us was one of injury to the right ureter from crush by the cab-wheel, and all the urine was accumulating in the right side instead of passing into the bladder. A localised peritonitis with encysted effusion appeared to be negatived by the absence of fever, tenderness, or pain on movement of the abdominal muscles or thighs. I pointed out that one of three things must have happened: (1) Either the ureter was simply bruised, and consequently so swollen or blocked by clot as to be impervious; or (2) it was completely torn across, and the urine was being poured out into the peritoneum, being limited by a layer of plastic matter; or (3) it was completely torn across without injury to the peritoneum, and the urine had formed a sac for itself in the post-peritoneal tissues. I had no doubt that one or other of these conditions was present, and, on the chance of the ureter being simply bruised and capable of recovering itself and allowing the hydronephrosis to discharge down the ureter in the usual way, I waited until September 3rd, simply keeping the child quiet and applying hot fomentations to the side. By this time, however, it seemed plain that no such issue was likely to take place, and that something must be done, as the swelling was becoming much larger and more tense each day, while the child lost his spirits and seemed to suffer considerably from the distension, sleeping badly, and being very fretful. The urine all the time was normal, and on September 3rd it is noted as acid in reaction, normal in appearance, of a specific gravity of 1021, and free from pus, blood, or albumen. Temperature 99°.

I now thought it necessary to aspirate the tumour and draw off the fluid. This I did with a fine needle, introduced midway between the last rib and the iliac crest and eight centimetres from the mid-line of the back. At this spot it is perfectly safe to puncture any form of renal tumour, and in a considerable number of cases in which I have operated in this way and seen others operate I have never observed any ill effect. The needle enters well behind the peritoneal reflection, and there are no other structures of any importance to be wounded if the point is not thrust too far. In this case, at the depth of about half an inch, the needle entered the collection of fluid, and of this I drew off forty-five ounces and a half. To the naked eye this fluid had all the characters of healthy urine. It was amber coloured, slightly cloudy; its specific gravity was 1010; it showed no deposit microscopically; it contained a quarter of albumen and a half per cent. of urea, also chlorides. Our diagnosis, therefore, was confirmed almost to certainty. But I was anxious to gain further evidence, especially as to the percentage of urea in the fluid, before pronouncing positively and determining on the more radical treatment of the case, as radical treatment could only be extirpation of the kidney ultimately. You will notice, gentlemen, that the secretion aspirated contained only a half per cent. of urea,

while the urine passed per urethram at this time contained 2½ per cent.; it also contained 25 per cent. of albumen. But you must also know that this is only what we might expect even with a perfectly sound kidney on the right side. For it has been shown by experiment on dogs that if there be an obstruction to the flow of urine through the ureter, the kidney is unable to excrete its full amount of urea, while it still preserves its power of secreting urine of low specific gravity, and hydronephrotic fluid contains albumen in many cases, if not all. Now, in this case, with a bruised or torn ureter, the right kidney would have to overcome considerable resistance as it forced its secretion into a slowly yielding sac, and therefore we should expect a low percentage of urea, just as in those cases where in the dog the ureter has been ligatured, and the urine collecting above the ligature has been tested. Of course the possibility of this being a localised peritonitic effusion had occurred to me, and the small trace of urea did not quite negative this. I therefore resolved to aspirate the collection a considerable number of times, at such intervals as should best relieve the child from the distension, watch the effect, and carefully test the fluid drawn off each time for urea and albumen, &c., and then drain the collection and see if the right kidney did not regain its power of eliminating urea, all obstacles being removed. I wished further to see if we could not gain some additional evidence as to the secretion being renal or not by observing what effect varieties of diet would have on the percentage of urea found in it. Besides these points of special clinical importance, there were several other matters of more purely physiological interest which it was desirable to note carefully. And here I may say, gentlemen, that, thanks to the care, patience, and thoughtfulness of Mr. Brown, House-Surgeon, and Mr. Young, the clerk to the case, who carried out my wishes in the most satisfactory manner, we have before us a most important series of observations, whether we regard them as a purely clinical record or as a physiological study. All praise is due to those gentlemen for the way in which they have done their duty, and it is particularly gratifying to think that the series of observations conducted for me by Mr. Young go far to fill up several gaps in our knowledge of renal affections which it was impossible before this to fill up for want of suitable cases for study in the human subject.

For you must know, gentlemen, that this case, though not quite the first of its kind recorded, is unique as regards the opportunities it offered for observation on the points to which I allude, also in having been made use of to elucidate many matters quite impossible of demonstration in the human subject, except in a case of the kind. And I may further tell you here that, so far as I can make out from a careful search through our home and foreign literature, only one case[1] at all like this has been put on record as a definitely diagnosed condition, while only two[2] more were shown to have been probably of the same nature after death, some months subsequent to the injury. These cases were published over forty years ago, and we need hardly be surprised if the records on many important points are scanty and defective, especially if we remember the advances made in the study of the chemistry of the urine since then.

Now, it so happened that in this case an early diagnosis was made, and that this received confirmation from the first tapping of the fluid accumulation. The evidence, however, was not absolutely beyond question. First, there was very little urea in the liquid aspirated; next, it contained a large quantity of albumen; again, it was desirable to see how soon it would refill to its former dimensions, and how far the opposite kidney was adequate. Now, it turned out that the tumour did refill, and just took about a week to reach its former size, so that I aspirated it once about every seven days for six weeks. Let us turn now to this table, in which I give you an abstract of the clinical charts prepared daily at the time, and see what we learn from what was observed. The charts themselves are very complete and elaborate, but it would occupy too much time to give them *in extenso*. They will always remain in the hospital register as one of the most complete records of the kind ever made, thanks to the clinical clerk to the case.

In the first place you will note that the amount of urine secreted by each kidney from the time of the accident up to the date on which I put in a drain-tube into the urinary collection on the right side differed very much. Out of forty-eight days, from Sept. 3rd to Oct. 22nd, the urine passed from the uninjured side during each twenty-four hours was carefully collected and measured on forty days. The average amount from this record was found to be exactly 10·5 ounces per diem (twenty-four hours). The eight days omitted were either Sundays or those on which the child had passed water into the bed, which could not be estimated. On the injured side, on the other hand, the amount secreted into the sac for the corresponding forty-nine days was almost exactly half—viz., 5·3 ounces per diem, taking the average of the amounts drawn off by aspiration once a week for the same period. Each aspiration emptied the sac completely. This contrast seems to show us that the right kidney having to overcome the resistance of an elastic sac, as it poured out its secretion, was unable to eliminate as much fluid as usual, and that the opposite kidney did extra work in compensation so as to yield 10·5 ounces daily, against its fellow's 5·3 ounces. But after free drainage of the urinary abscess was established on Oct. 23rd, and all obstacles to the secretion of the right kidney were removed, a perfect balance was established both as to quantity and quality, and for the twenty-two days, between Oct. 23rd and Nov. 19th, on which a careful record was made, the average on the left (uninjured) side was 7·8 ounces, as against 7·4 ounces on the right (injured) side. This, you will observe, corresponds almost exactly with the daily amount yielded by the two organs together before the drainage.

Next you will note that after the removal of the right kidney on Nov. 19th the remaining organ was at once able to take over the functions of the two kidneys, and not only this, but actually excreted daily more urine than both had secreted together before the operation, the days succeeding operation, 21st, 22nd, 23rd, and 24th, showing respectively 7, 26·5, 26, and 36 ounces. This was no doubt greatly due to the fact that the child lived on fluid food exclusively for some days after operation.

Then as to specific gravity, you will note that on the sound side all this time it remained fairly constant, its average being generally between 1021 and 1025, except during the week in which the patient was given an almost purely non-nitrogenous diet, when it fell to 1007. (After Oct. 22nd the readings for the individual days are given in the Table.) During the corresponding seven weeks the disabled kidney registered 1010, 1008, 1006, 1010, 1007, 1004, and 1010 respectively, the lowest figure tallying with the non-nitrogenous diet.

Next, the average amount of urea excreted was pretty constant on the sound side for each week, except when it reached 2·85 during the highly nitrogenous diet, and fell to 0·71 for the last days of the purely non-nitrogenous diet, and it rose at once again the next week on ordinary diet to 2·75. In strong contrast to this we have a very small average percentage of urea eliminated by the opposite kidney while working against obstacles of pressure. The largest record is seen in the fluid first drawn off, and yet this was only one half per cent. For the next five weekly aspirations it was constant at 0·1 per cent., in spite of change of diet, with the exception of one occasion, when it was 0·15. During the week of non-nitrogenous diet it fell to 0·05, and the next week rose to its former figure of 0·15 on resumption of ordinary dietary. But after Oct. 22nd, when the drain-tube was inserted into the urinary collection, the percentage of urea on the injured side steadily rose from 0·15 to 2·6, all resistance to excretion being removed from the right kidney (*vide* Table.) Both kidneys secreted acid urine throughout. On one or two occasions it is put down as alkaline, but I have reason to believe that it was not taken quite fresh at these times.

The urine from the sound side was always free from albumen, that from the urinary abscess contained from 20 to 50 per cent. of albumen always. This was no doubt derived from the serum and lymph secreted from the walls of the sac, which usually rendered the fluid drawn off cloudy to a small extent.

The urea excreted by the remaining kidney after the other had been removed gradually rose from 1·8 to 2·05; or if we take the amount in grains per diem, we find on the 21st, 75·6 grains; 22nd, 127·2 grains; 23rd, 124·8 grains; 24th, 164·1 grains; 25th, 121·4 grains; 26th, 177·8 grains. A glance at the average temperature of these days, taken generally about every hour, will show that the amount of urea was probably influenced by the combustion of tissue

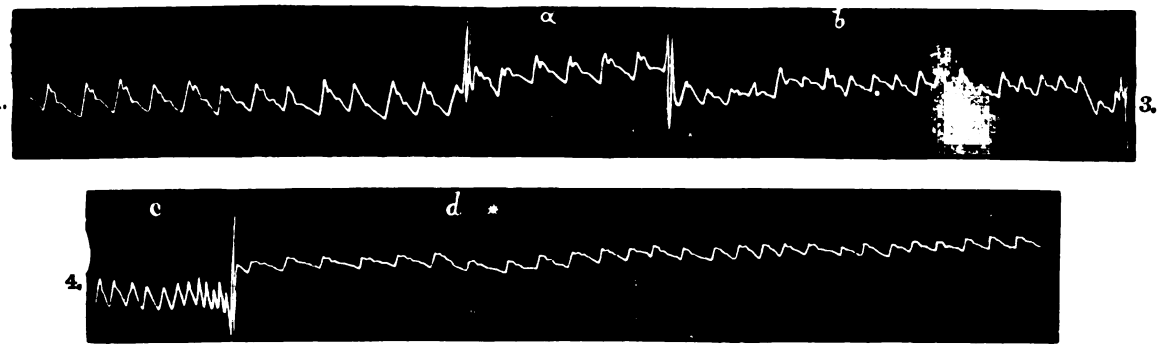
going on, the highest percentage being observed on the day when the average temperature was highest viz., 101·7°.

Now, gentlemen, I had accumulated almost all these facts, except the last data, before deciding the question of removal of the right kidney, although it appeared urgently necessary. They proved beyond a doubt that the fluid in the right flank was urine, and that the kidney secreting it was quite healthy, doing its work as to quantity and quality normally the moment the obstacles to its excreting forces were removed. They proved, further, that the left kidney was perfectly healthy, and able to take on double work if required. On several days it secreted quite as much as the average quantity of the two organs for the week, and during the highly nitrogenous dietary its elimination of urea rose as high as over 3 and even 4 per cent., while that of the other kidney remained unaffected. From this aspect of the case, therefore, there could be no objection to the removal of the offending kidney.

But other points demanded consideration. First, Is the operation of nephrectomy a dangerous one? To this I may reply at once that if we have a healthy kidney and a sound individual to deal with it is not so. Without going into details, I may tell you that I have collected a considerable amount of evidence to show that the organ may be dealt with very freely without danger when it alone is in question. Cases are on record where it has been slit open and prolapsed through a lumbar wound, and has been removed without the slightest constitutional disturbanee. It has even been prolapsed through a wound and replaced, and recovered completely. We are not speaking now of its removal for diseased conditions, which is quite a different matter.

The next question to be decided was, What necessity was there for any operation at all? The answer to this is to be found in the child's condition after the injury and the history of the only analogous cases recorded.[3] You will remember that this child had an accumulation of urine in the retro-peritoneal tissues, which was increasing at the rate of about two pints a week. From our maturer observations it seemed clear that the fluid was not contained in the distended pelvis of the kidney, and was also not encysted in the abdominal cavity. Now, in addition to the discomfort and distress due to this collection, which were both very marked, there was the danger of rupture of the sac into the peritoneum at any time, and death as a probable consequence. In addition to this there was the danger of free suppuration in the sac; this seemed by no means remote, for with each aspiration of the fluid there was noticed more turbidity from lymph, although the strictest antiseptic precautions were observed. There seemed to be no hope in this case of an atrophy of the organ, which was healthy and vigorous; in the meantime, even if this were remotely possible, some immediate relief was necessary for the child, and simple aspiration was resorted to. And while this showed us the hopelessness almost of looking for gradual atrophy of the organ, it was plain it could not be resorted to for a continuance, and of course it increased the risks of suppuration of the sac. Then I tried a more perfect drainage of the sac as a palliative. But it was plain after a few weeks' observation of this measure that the child's condition was not improved, and that he ran increased risks. The slightest block of the drain-tube was followed by the severest constitutional disturbance, and on several occasions this was alarming in the highest degree, the temperature on one occasion reaching 105·6°, and several times exceeding 104°. Such blockages appeared to be unavoidable on account of the deposit of phosphates in large amounts in the cavity around the tube. On several occasions these deposits had to be removed in masses as large as beans, and could only be expected to re-form in consequence of the free flow of urine from the healthy kidney. Should the child leave the hospital and be transferred to the care of his parents, the dangers from this side would be much increased of course. Finally, if he should be freed in any way from the danger of blocking of the drainage opening, his condition would be very miserable with a constant flow of half the daily amount of urine from his side for the rest of his life, which no urinal could save him from. There appeared upon all these grounds no choice left to me but to remove the organ which was furnishing this abundant secretion. This I accordingly did as described, and the result so far has been satisfactory. The operation itself, which was strictly antiseptic, and which you have seen, requires but brief notice. It consisted in an incision, about three inches long, immediately below and in the direction of the last rib and commencing just behind the external border of the erector spinæ muscle; then division of the layers of muscle and aponeurosis; then clearing the whole surface of the kidney from its surrounding fat with the finger; next transfixion of the pedicle with an aneurysm needle armed with carbolised twisted silk, and tying the pedicle in two portions; then in drawing the kidney out of the wound, and a further ligation of the vessels *en masse* on the proximal side of the first; after this the pedicle was divided with a snip or two of the scissors and slipped back into its place; then suture with silver stitches and dressing with salicylic wool, a drain-tube being left in the original



drainage opening. The whole operation lasted twenty-three minutes, and presented no difficulty except in the ligature of the pedicle, where I lost some time in tying *in situ* instead of drawing the organ out of the wound and then placing a ligature round it. I was anxious, however, to avoid dragging on the pedicle and its nerves, as this appears, in some cases at all events, to add much to shock. In this case there was no marked shock at any time as indicated by the pulse, which was carefully observed all through. Another interesting observation which I have often wished to make I was able to record in this case. This consisted in taking a sphygmographic tracing of the radial pulse immediately before, during, and after the act of ligaturing the pedicle. This was kindly undertaken for me by Mr. Horsley while I was proceeding with the operation, and you have seen the tracing (*vide* Chart). As he told you, it does not indicate any particular shock, but shows what is usually noticed when a large artery is ligatured. A very short time after the operation the child came to himself and seemed remarkably well, and soon began to talk with the other children in the ward. His temperature has risen on several occasions, but without any other alarming symptom, and probably as the result of blocking of the drain opening with some of the phosphatic deposits which have not yet been thrown off from the walls of the sac, but are daily coming away. He is now, three weeks after operation, enjoying his ordinary diet, and cheerful and well.[4] The glands in his neck noted as much enlarged for the last two

[3] Loc. cit. Two of these died within ten weeks after the accident, the other was lost sight of after the tapping.

[4] The child left the hospital and went home on Jan. 8th, seven weeks after the removal of the kidney. He had still a very small sinus in the side, yielding about a drachm of pus daily, but was otherwise well.

years and a half, and fluctuating long before the operation, have increased in size and have been since opened, giving exit to a considerable amount of pus. The rise of temperature may be accounted for, to some extent, by the maturing of these abscesses, for he has been much relieved by their evacuation. At all events his present state is satisfactory, and I hope soon to be able to bring him down here and show him perfectly convalescent.

The kidney removed proved to be perfectly healthy macroscopically and microscopically, and the pelvis was not dilated. The ureter appeared to be divided just below the seat of rupture. The lower end of the kidney formed part of the wall of the urinary abscess, and was covered with lymph and phosphates, showing the correctness of our diagnosis that we had to deal here with a retro-peritoneal collection of urine, not a true hydronephrosis. Perhaps the best name for this condition is that used above—viz., "urinary abscess"; or if this is objected to on account of the small amount of inflammation, we might call the condition pseudo-hydronephrosis.

The accompanying tracing was taken on one continuous slip, which was run through the sphygmograph as the operation proceeded, and was stopped from time to time when a fair sample of pulse was procured, but the instrument and limb were not otherwise touched. The slip is only cut in two for convenience of printing, the division being made at one of the stops (3), which corresponds directly with 4. Pulse 118. A long tracing (normal) was first taken as the child lay on the table under chloroform, and this terminates at 1, where the operation commenced at 3 P.M. After a time there appeared a slight rise with normal wave still (*a*); then, corresponding to the manipulation of the kidney, some irregularity is shown (*b*); then a fall with a different kind of irregularity (*c*); then a gradual rise, slightly increased, perhaps, by the ligature of the renal artery at **d*, with a lower stroke. Pulse 140.

REMARKS ON THE

CIRCULATION OF THE BLOOD.

HISTORICAL NOTICE OF THE DISCOVERY THAT THE VEINS OF THE BAT'S WING, WHICH ARE FURNISHED WITH VALVES, ARE ENDOWED WITH HEART-LIKE RHYTHMICAL CONTRACTILITY, WHEREBY THE BLOOD IS ASSISTED ONWARD IN ITS COURSE TO THE HEART: A PROTEST AGAINST EFFORTS MADE TO IGNORE A CRUCIAL FACT IN NATURE.

BY T. WHARTON JONES, F.R.C.S., F.R.S., &c.

HAVING by experimental research elucidated the *artificium admirabile* of the circulation of the blood in the extreme vessels of the frog's web (as recorded in Guy's Hospital Reports for October, 1850), I applied myself to the study of the same subject in the wing of the bat, and had not observed long before peculiar contractions of the veins engaged my attention. The bat I first examined was of the large brown species, but it proved so restless that its wing could not be retained sufficiently steady under the microscope to admit of any accurate discrimination of the nature of the peculiarity referred to.

Having procured specimens of the grey house-bat and of the long-eared bat, I found them quiet animals, and in their wings, spread out under the microscope, I was able to make prolonged and detailed observation of the flow of blood in the extreme vessels. The result was that I discovered rhythmical constrictions of the calibre of the veins going on, whereby the course of the blood in them towards the heart was promoted, while the valves with which they are furnished prevented regurgitation. The systole or constriction of the calibre of the veins was found to be caused by rhythmical contraction of the muscular walls of these vessels, whilst the succeeding diastole took place by sudden elastic recoil. Besides making this discovery, I traced the extreme ramifications of the arteries into the capillary network, and thence the origin of the radicles of the veins, thereby correcting the mistake which had been shortly before made by Mr. (now Sir) James Paget, that in the bat's wing extreme arteries open directly into veins, and that this might be a provision of nature connected with the hibernation of the animal.

Impressed with the importance of the discovery I had made of this *artificium admirabile* for promoting the onward course of the blood in the bat's wing, which by its length is so remote from the full influence of the heart, I forthwith prepared an account of it, illustrated by exquisite drawings taken from life, for presentation to the Royal Society. My discovery I kept secret until I had given in the paper, but in the meantime confidentially communicated it to my friend the late Professor Graham, and entrusted to his care a transcript in order to guard myself against any anticipation *per fas aut nefas*. After the paper was given into the Royal Society, but before it was read, I showed Mr. Huxley the wing of a bat under the microscope, and pointed out to him the phenomena I had discovered.

By this time the discovery had come to be talked of among persons who seem to have been rather chagrined than pleased with this important addition to our knowledge of the mechanism of the circulation of the blood. Happening to fall in with a circle of such friends, Mr. Huxley heard Dr. W. B. Carpenter remark slightingly that he did not "believe Mr. Wharton Jones's observations to be correct." "But I have seen the phenomena," interposed Mr. Huxley; whereupon the gentlemen turned to Mr. Paget, who was present, and regretfully expressed their surprise that he should have missed detecting the fact when making observations on the bat's wing for his lectures on Inflammation at the Royal College of Surgeons in 1850. Mr. Paget had indeed noticed contractions of the veins, but overlooked their heart-like rhythmical character, comparing them merely to the tonic muscular contractions of arteries.

The late Mr. Thomas Bell, Professor of Zoology in King's College, was at this time Physiological Secretary of the Royal Society, and as soon as the paper had been delivered to the assistant secretary, I wrote to Mr. Bell telling him of the fact. In reply this gentleman went somewhat out of his way in dwelling on the excellence of an article on Veins which his nephew, Dr. Salter, had just prepared for the Cyclopædia of Physiology, and betrayed, as it appeared to me, chagrin that it had not fallen to the lot of his nephew to make the discovery I had made. Though the fact is of such scientific importance, the prestige of its discovery has been ignored as much as possible, something after the manner of the ostrich which buries its head and eyes in the sand to escape observation when pursued.

On the occasion of my discovery being brought before the Royal Society, the late Sir John Herschel, vice-president, occupied the chair at the meeting, and Mr. Bell read the paper. When a reference to the illustrative drawings came to be made, I saw him fumble among some loose papers on the table as if to pick up the drawings to exhibit, but no drawings were forthcoming. This, I remember well, caused me some misgiving as to their safety. An abstract of the paper, of which a copy is here given, was duly printed in the Proceedings:—

"'Discovery that the veins of the bat's wing, which are furnished with valves, are endowed with rhythmical contractility, and that the onward flow of blood is accelerated at each contraction.' By T. Wharton Jones, F.R.S., Fullerian Professor of Physiology in the Royal Institution of Great Britain, &c. Received November 20th, 1851.

"The author finds that the veins of the bat's wing contract and dilate rhythmically, and that they are provided with valves, some of which completely oppose regurgitation of blood, others only partially. The act of contraction of the vein is manifested by progressive constriction of its calibre and increasing thickness of its wall; the relaxation of the vessel, by a return to the former width of calibre and thickness of wall. The rhythmical contractions and dilatations of the veins are continually going on, and that, on an average, at the rate of ten contractions in the minute. The contractions *centrad* and *distad* of a valve appear to be simultaneous, as also the dilatations. During contraction the flow of blood in the vein is accelerated, and on the cessation of the contraction the flow is checked, with a tendency to regurgitation, which brings the valves into play. But this check to the onward flow of the blood is usually only momentary; already, even while the vein is in the act of again becoming dilated, the onward flow recommences and goes on, though with comparative slowness, until the vein contracts again. It is the heart's action which maintains the onward flow of blood during the dilatation of the vein, whilst it is the contraction of the vein, coming in aid of the heart's action, which causes the acceleration. The valves are composed sometimes of but a single flap, some-

times of two. In the situation of a valve and *centrad* of the insertion of its flaps the veins present the usual dilatations or sinuses. The valves are a reduplication of the clear innermost coat of the vein, with sometimes an intervening layer of cellular tissue. The veins closely accompany the arteries, the nerve only intervening. The author further finds that nowhere do the arteries and veins of the web of the bat's wing directly communicate, as has also been alleged, the only communication being the usual one through the medium of capillaries.

"In an appendix to this paper, the author describes the result of his microscopical examination of the structure of the veins and arteries. Both artery and vein have a middle coat of circularly disposed muscular fibres; but the appearance of the fibres is different in the two vessels. The fibres of the vein are $\frac{1}{3700}$ in. broad, pale, greyish, semi-transparent, and granular looking. In general aspect they very much resemble the muscular fibres of the lymphatic hearts of the frog; but in none did the author detect an unequivocal appearance of transverse marking. The fibres of the middle coat of the artery are not so pale looking, are clearer, and exhibit a more strongly marked contour.

"In another appendix the author states that the veins of the ear of the long-eared bat were found not to be endowed with rhythmical contractility, and that the muscular fibres of their wall present microscopical characters similar to those of ordinary veins."

By-and-bye the paper itself was ordered by the Council to be published in the Philosophical Transactions. So far well. But here comes the mystery as to the drawings. Mr. Bell wrote to me saying that they were not to be found, and asking if I could supply another set. Fortunately, I had preserved the original sketches, and they admitted of being touched up, so that engravings could be made from them sufficiently illustrative of the essential points of the subject. They were, however, poor substitutes for the exquisite drawings which had, it was alleged, disappeared.[1] There is always a chink between the plates of one's armour, and thus it was that notwithstanding all the precautions I had taken to ensure my paper against any encroachment *per fas aut nefas*, I had to lament the loss of the drawings. No explanation was offered to me by Mr. Bell as to how they had disappeared, and of course I could not well ask for one. A calm review now, after the lapse of thirty-two years, however, of the circumstances at the time, and of what came to my cognisance subsequently, fails to disabuse my mind of a suspicion that the drawings were not fairly dealt with.

This discovery of the heart-like, rhythmical contractions of the veins of the bat's wing was a crucial one in the history of the circulation of the blood, inasmuch as it shows how, by the new force thereby brought into play, the onward movement of the blood is and may be promoted when by the distance of an organ from the heart the force thereof would be inadequate. As an example of design, the mechanism in question is simply marvellous. The veins of other parts of the bat's body are not similarly endowed with rhythmical contractility, as may be seen in the ears of the long-eared bat, which admit of examination under the microscope; these organs being so near the heart that the circulation in them requires no additional power for its maintenance.

I have no hesitation in boldly claiming for the discovery of the heart-like, rhythmical contractions of the veins of the bat's wing and the promotion of the onward course of the blood thereby, the third place in the history of the circulation of the blood; the first being Harvey's exposition of the true mechanism of the action of the heart and great arteries, whereby the blood is driven to all parts of the body through the arteries and back to the heart through the veins; whilst the second was Malpighi's discovery of the capillary vessels and the passage of the blood through them from the extreme arterial ramifications to the radicles of the veins—a discovery which Harvey anxiously sought to make, but failed for want of the means of investigation. In a clinical lecture on the circulation of the blood, which I delivered at University College Hospital a few years ago, and which was printed in THE LANCET, I remarked that if Harvey had been one of the party comprising among other eminent philosophers, Christian Huyghens, to whom Leuwenhoek tells us he demonstrated the capillary circulation in the tail of a minnow under one of his simple microscopes (the lens ground by himself), he (Harvey) would have danced for joy. To this I may here add that if Harvey had been present that evening at 35, George-street, Hanover-square, London, when I showed Mr. Huxley in a bat's wing under the microscope the rhythmical action of the veins, and the acceleration of the onward course of the blood to the heart thereby produced, while valves[2] prevented regurgitation, he (Harvey) would, I am sure, not only have danced but sung paeans also.

In 1656 Harvey gave the College of Physicians an estate, part of the income from which was to endow a solemn oration to be delivered annually in commemoration, among other things, of "any addition made to the sum of medical science." The elucidation of the mechanism of the circulation in the extreme vessels was, we have seen, an object of anxious solicitude with Harvey, and doubtless the discovery of the heart-like action of the veins in the bat's wing would have been considered by him above all things as coming under the category of "an addition to the sum of medical science," and therefore ought to have been at once recognised as such at the College of Physicians. The discovery of the heart-like rhythmical actions of the veins of the bat's wing, with valves in operation to prevent regurgitation, though made thirty-two years ago, has, however, never been mentioned in any one Harveian Oration that I am aware of. Such shutting of the eyes to facts in nature is only equalled in disingenuousness by the pretence of seeing things that do not exist in nature. Some years ago, when Dr. Burdon Sanderson, my then colleague at University College, and now Professor of Physiology in the University of Oxford (the same gentleman who undertook to show me the emigration of white corpuscles of the blood from the interior of small vessels, but did not keep his appointment), was about to deliver the Harveian Oration at the Royal College of Physicians, I wrote to him suggesting that he should go into the subject, but he declined to do so. Whether he had ever made himself acquainted with the facts by observation, I did not at the time know. It being his duty as a professor to teach his pupils crucial facts in physiology, I presumed that he had done so. I now find, however, that such could scarcely have been the case, judging by the meaningless passage in his syllabus of lectures—viz., "in certain animals veins contract rhythmically," and this without any reference to the effect on the flow of blood. Whatever may have been taught in lectures on the subject to students, I have found that in the books on physiology which have come under my notice the rhythmical contractions of the veins of the bat's wing are either not at all mentioned, or, if referred to, mentioned in such a manner as to indicate that the author had never seen fit to look on the original, or to read my paper, or even the abstract of it, as intercalated above. In my "Inquiry" concerning the alleged primary active dilatation of small arteries under the influence of imaginary vaso-dilator nerves, the shortcoming of McKendrick's Physiology in this respect was commented on. The reference to this book reminds me that the author of it, the Professor of Physiology in the University of Glasgow, also holds, or recently held, the Fullerian Professorship of Physiology in the Royal Institution of Great Britain. As the founder of this professorship, Mr. John Fuller of Rosehill, was a distant kinsman of mine, and as I had the honour of holding the office thirty-two years ago, I regard it with some interest. It was during my incumbency that I discovered the heart-like action of the veins in the bat's wing. I therefore took the opportunity in the course of my lectures to give the audience an account of the admirable mechanism. Judging from Professor McKendrick's lectures at Albemarle-street as reported, I fear his account of the subject therein has been as far from the facts in nature as are the statements in the Text-book of Physiology for the use of his class in the University of Glasgow here criticised.

(To be concluded.)

[1] In supplying the new set of drawings, I requested that they might be returned to me after the engravings were made, and they were accordingly returned.

[2] My discovery thus included the observation for the first time of valves in action in the veins of a mammiferous animal, such as no doubt takes place in the human body.

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the quarterly meeting of the directors of this fund, held on the 13th inst., Sir W. R. E. Smart, K.C.B., M.D., Inspector General, in the chair, the sum of £82 was distributed among the several applicants.

RHIGOLENE: AMYL HYDRIDE.

BY BENJAMIN WARD RICHARDSON, M.D., F.R.S.

THE annotation on Rhigolene in THE LANCET of the 10th inst. requires, if I may venture to say so, some slight correction and supplement. Rhigolene is the crude or impure hydride of amyl, $C_5H_{11}H$, and is the lightest fluid of the petroleum series. It has a vapour density of 36, taking hydrogen as 1; a specific gravity of 625, taking water as 1000; and a boiling-point of 30° C. (86° F.) It is insoluble in the blood at the natural blood temperature. The fluid in the crude state has a faint but pleasant odour and a slight taste; it causes no irritation, and when raised into vapour can be inhaled without difficulty. It mixes with anhydrous ether in all proportions.

Rhigolene is not in any sense a local anæsthetic by virtue of causing insensibility from its absorption. It cannot, in fact, be absorbed locally. It can, however, be dispersed, like ether, in the form of spray for producing cold; in that way it can be used for causing anæsthesia by extreme cold, and so used is valuable for quick and superficial freezing. Within a few weeks after the appearance of my original essay on Ether Spray in 1866 a merchant in the City sent me a specimen of rhigolene, as "a fluid lighter and less soluble than ether, and with a lower boiling-point," he having read that I wished for such a fluid. I at once brought the fluid into service for spray, and found it most effective for rapid freezing. In dentists' practice it soon became very popular. The cold produced by the rhigolene spray is so intense that I have seen a portion of the skin rendered hard, white, and insensible by it within two seconds. At first sight this promises well, but as a general fact the action is too rapid. The superficial layer of surface that has been so rapidly frozen is rendered a non-conductor, and deep freezing and deep insensibility are prevented. Finding this out, I constructed the *compound anæsthetic ether for local anæsthesia*, consisting of rhigolene and anhydrous ether in equal parts. That fluid has been very largely used from the time when it was brought out, and is still in use as largely, I believe, as ever.

Rhigolene may be used alone, as spray, in some cases. For inserting a suture it answers well, the point where the needle is to enter being made insensible by it instantly, and quite long enough to save the pain of the puncture. It can be used for painless extraction of loosened stumps of teeth and for puncture of a superficial abscess. Directed as spray over the closed eyelid, held tense over the ball of the eye, it causes a brief insensibility of the conjunctival surface, the conjunctiva, an almost insulated surface being more easily rendered either sensitive or insensitive by local influences than other mucous surfaces, which rest on a deep cellular basis, or than the cutaneous surface.

Rhigolene, though not in itself a local anæsthetic, is capable of producing general anæsthesia on administration of its vapour by the lungs. Purified by distillation, it is a colourless and odourless fluid, and is even agreeable to breathe. It causes general anæsthesia with great rapidity, often within the minute, with recovery in two minutes. In my report to the British Association for the Advancement of Science at Exeter in 1869 (Trans., p. 412), I spoke favourably of it for general anæsthetic purposes; but later experiments with it showed me that owing to its insolubility it was dangerous—as dangerous as amylene. I therefore ceased to advocate its introduction for general anæsthesia.

Readers who may be interested in this fluid may turn to my Exeter Report upon it for some other curious and useful applications of it, of which I will briefly notice three.

For Burns.—I found that camphor and spermaceti dissolve in rhigolene freely. I therefore made a saturated solution of spermaceti and rhigolene, and then added camphor until that ceased to be dissolved. The solution so formed was applied with cotton-wool to burns. The evaporation of the fluid gave instant relief to pain, and left over the surface a thin layer of spermaceti and camphor, which excluded air and gave an excellent dressing. One drachm of spermaceti and one drachm of camphor will dissolve in two fluid ounces of rhigolene.

For Iodine Disinfection.—I found that the fluid would take up iodine. I used it, consequently, for making an iodine solution, and employed the solution for various purposes. Applied to the surface of a fetid wound, it leaves the iodine on the surface in finest subdivision. Sprayed into the throat, it is very useful in malignant or fetid ulceration, one or two injections of the spray being quite sufficient to leave a free portion of iodine on the surface. Inhaled as a weak solution, it affords a means of allowing iodine to enter the respiratory tract, a little iodine being always carried over with the vapour. The strength of the iodine solution which I use is five grains of iodine in one fluid ounce of rhigolene. One of Gamgee's excellent absorbent pads treated with half a fluid ounce of this solution becomes in a few moments a most perfect iodine sponge, applicable for a variety of useful purposes.

For Antiseptic Use.—By shaking a strong solution of ammonia with the rhigolene and then decanting off the water, I obtained an ammoniated solution which acts as an excellent antiseptic, the vapour of which can be inhaled. The same solution charged with camphor is very useful for the preservation, temporarily, of natural history specimens. Dead objects are perfectly preserved by putting them for a short time into a bath of the solution, letting the fluid escape as vapour, and leaving the camphor in the tissues.

Manchester-square, W.

ON FUNCTIONAL AND FALSE MURMURS.[1]

BY J. KINGSTON FOWLER, M.A., M.D.,
ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE MIDDLESEX HOSPITAL; ASSISTANT PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION.

WHEN we find one of the normal sounds of the heart replaced or accompanied by a murmur we have, as a preliminary step to a complete diagnosis, to give an answer to two questions, Is this sound produced within the heart? If so, does it indicate organic disease of a valve? That a murmur may exist independently of structural lesion is a fact so well recognised that it is only necessary to mention it, but I doubt whether the great frequency with which such a condition is met with is fully appreciated by those who have not paid especial attention to the subject. At a clinical demonstration which I gave last year at the Brompton Hospital, I was able to show fourteen patients at that time under my care in the out-patient department, in each of whom a murmur was present which, although simulating the altered sound indicative of organic valve disease, was really due to some extrinsic or functional condition.

There are, I imagine, few physicians who have not at some time met with a patient who has told them that he is quite aware that his heart is diseased, as his life was refused for insurance on that ground years ago, whilst on examination, although something abnormal has been detected in the heart's sounds simulating the effect of organic change, it has proved to be nothing more than a false or functional murmur. This subject derives an additional importance from the fact, now becoming generally recognised, that acute rheumatism, certainly the most common cause of endocarditis, is frequently accompanied by changes in the heart's sounds almost identical with, and easily mistaken for, the results of organic disease. An important contribution to our knowledge of the conditions under which such murmurs may be found has been lately made by Dr. Angel Money in a paper recorded in vol. xlv. of the Medico-Chirurgical Transactions, "On the Great Frequency of Cardiac Murmurs in the Puerperal State." As the result of a systematic examination of 111 cases, a murmur was present in no less than 84, or rather more than 75 per cent. Of these only 2 were of undoubted organic origin; in 51 cases the sound resembled an ordinary endocardial murmur, and first appeared most commonly a day or two after delivery.

The various conditions which may give rise to these functional and false murmurs may be conveniently classified thus:—1. Displacement of, or pressure upon, the heart, the result of previous disease of the (*a*) lung, (*b*) pleura, or (*c*) thorax. 2. Effusion into the pleural cavity. 3. Changes in the pleura of the præcordial area. 4. Changes in the lung overlying the heart. 5. Changes in the pericardium. 6. Altered conditions of the muscular walls of the heart. 7. Altered conditions of the blood.

1 (*a*) *Displacement of the Heart, the Result of old Disease of the Lung.*—As a result of the contraction of a cavity, say

[1] Read before the Medical Society of London, October 27th, 1884.

in the left apex, the heart is frequently found displaced upwards. Under these circumstances a systolic murmur is often heard in the second or third left interspace, having its maximum intensity about two inches from the edge of the sternum. The presence of the cavity and the indurated lung surrounding it intensifies the murmur, which I have in some cases found to be so distinct as to be audible over the greater part of the left chest. This sound, though more commonly suggesting aortic disease or a hæmic murmur in the pulmonary artery, I have known to be mistaken for the murmur of mitral regurgitation. When the cavity is detected and the displacement of the heart recognised the differential diagnosis should not be difficult, especially when the rare association of phthisis and valvular disease is remembered.

(*b*) *Pressure upon the Heart, the Result of old Disease of the Left Pleura.*—Perhaps of all the false murmurs which we are now considering none are more common, or present greater difficulties in diagnosis, than those caused by pressure upon the heart resulting from the contraction of the left side of the chest after an attack of pleurisy. The pleura is probably thickened, and the lower lobe of the left lung partially collapsed, and at each systole a sound is produced by the sudden impact of the heart displacing the air in the larger bronchi. This may be audible not only at the apex and in the axilla, but also at the angle of the left scapula, in the trachea, and in the mouth.

In one patient under my care, who was shown at the demonstration above referred to, a systolic murmur produced in this manner was distinctly audible to those present at a distance of more than a yard from the patient. When he held his mouth open a puffing sound was heard, which may be imitated by saying Hah! hah! during expiration. In this case an aneurysm of the aorta with pressure on the trachea had been suspected. I may here remark that the presence of a systolic murmur in the trachea, which has been said to be diagnostic of aneurysm of the aorta, is far from having such an important significance. I have several times detected it even during attacks of functional palpitation.

(*c*) *Displacement of the Heart from Deformity of the Chest.*—I have met with several instances of murmurs originating from this cause. One particularly I can recall in a woman, in whom the lower part of the sternum was depressed to such an extreme degree that by careful measurement it was clear that its posterior surface was only separated from the spine by a distance of about two inches. The chest was shaped like a crescent with blunted horns, the left one holding the heart, which could be literally grasped by the hand and all its movements distinctly felt. Here a loud systolic murmur was present. Latham, in his Lectures,[2] thus graphically describes such cases:—"Strange things happen to the heart when the chest is deformed. There is an end of our pretending to calculate what its condition may be by listening, and feeling, and percussing. Its sounds, and impulses, and resonances, be they what they may, are now worth nothing at all as guides to diagnosis. The heart is dragged from its proper seat and imprisoned in some strange place, and perhaps turned almost topsy-turvy by the encroachment of the vertebral column and approximation of the ribs. And thus cramped and hooped about with bone, at every movement it gives a jar that may be felt and a sound that may be heard in every part of the chest; and this sound which is thus conveyed to a distance is seldom the natural sound, but a loud whiz, the same in kind and the loudest in degree which belongs to mechanical impediment from valvular disease. And mechanical impediment there is, but valvular disease there is none. The weight and pressure which the heart or its large vessels sustain from the hard framework of the chest raise the impediment, and throw it in the way of the circulating blood."

2. *Effusion into the Pleural Cavity.*—In some cases of pleural effusion, more frequently, I believe, when the left side of the chest is affected, a loud and prolonged systolic murmur may be heard either near the apex or at the base of the displaced heart. This murmur so exactly simulates that of mitral regurgitation that when heard for the first time it is difficult to believe that the patient is not suffering from valvular disease in addition to his pleurisy, or the case may even be regarded as one of hydrothorax resulting from the condition of the heart. I have met with only two examples of this murmur, which I believe to be of very rare occurrence; both were cases in which there was a very large serous effusion on the left side; in one of them, as tested by the manometer, there was an absolute pressure within the pleural cavity. Such a condition is, it appears to me, unfavourable to regurgitation through the mitral orifice, but likely to produce a murmur either in the aorta by pressure upon the vessel, or, what is more probable when the murmur is localised at the apex, within the ventricle itself. The murmur completely disappears on the removal of the fluid from the chest.

3. *Changes in the Pleura of the Præcordial Area.*—Friction murmurs having their origin in some change in the præcordial pleura are very common. They are probably produced by the impact of the heart against the chest wall forcing back the thin margin of the lung, the pleural covering of which is roughened. This sound may be systolic in time, but is more commonly of a to-and-fro character, when it may suggest that aortic regurgitation is present. It is superficial and rough, localised, and generally becomes more distinct on firm pressure with the stethoscope. When the breath is held, after a deep inspiration, the murmur usually disappears, as then the lung is fixed and is uninfluenced by the contractions of the heart. It is important to note that a true pleural friction sound can usually be detected in the neighbourhood of these murmurs, which are commonly not exactly systolic or diastolic in time.

4. *Changes in the Lung overlying the Heart.*—In the subjects of pulmonary phthisis it is very common to hear a systolic murmur about the apex of the heart which closely resembles the murmur of mitral regurgitation, whereas, as is well known, these two conditions are rarely associated. The sound is caused by the impact of the heart upon lung tissue partially consolidated, producing an audible sound by displacement of the air in the bronchi in a similar way to that already described. It is almost always most distinct during expiration, is superficial, high pitched, and disappears when the breath is held after a deep inspiration, and often becomes inaudible when the patient lies down. This murmur may sometimes be heard in the axilla and at the angle of the left scapula, and in such a case may be readily mistaken for one of mitral regurgitation. The most common site of a murmur thus produced is not, however, at the apex, but in the second left intercostal space, about two inches from the sternum. In doubtful cases of early phthisis at the left apex the presence of this morbid sound is strongly suggestive of lung consolidation. In many of these cases, however, it is probably due to some displacement of the pulmonary artery, the result of the disease of the neighbouring lung. It was not until some time after I had, as I thought, discovered this sign and marked its association with phthisis—as probably many others had done before me, for there is little new in the field of physical diagnosis—that I found it had been fully described by Latham, who thus refers to it:—

"Of such a murmur, often audible in this situation exclusively, I am certain as a matter of fact, and certain, too, of its very remarkable accompaniments. I have witnessed it in those who were undeniably consumptive, or in those who were too justly suspected of being so. I cannot say in what proportion of the phthisical it occurs, but I am continually meeting with it."[3]

(To be concluded.)

SUGGESTIONS ON THE

GENESIS OF DISEASE FROM AN EVOLUTIONARY POINT OF VIEW.

BY W. HENRY KESTEVEN, M.R.C.S.

IT has occurred to the writer that the adoption of the germ theory of disease necessarily involves the application of the theory of evolution, and that here may be found a means of accounting for the genesis of the various forms of disease. Germs are living matter; they must therefore be under the influence of those laws and forces which condition all living matter. The most important of these, or the one that most interests us in the present connexion, is the law of natural

selection; and it must be that germs, in common with other forms of life, are under the influence of this law in some shape. Natural selection is a general term which embraces all other modes of selection, or provision for the "survival of the fittest." Among these is sexual selection, and taking a broad view, we may also include selection by man. In order, then, to the attainment of greater exactness may we not give a name to that form of natural selection which has been potent in bringing about the variations in the characteristics of those germs, to which the differences in the forms of disease are due? Such a term may be found, I would suggest, in "tissue selection," as indicating the special means whereby the constitution of the germs has been modified. The actual origin of the bodies which have received the names of germs is not at present determinable, and to say that they do not originate *de novo*, in decaying matter or elsewhere, is only to reaffirm the axiom now pretty generally admitted, *Omne vivum e vivo*. The fact that meets us here is that these germs, call them bacilli, vibriones, bacteria, or what we will, are met with almost universally in the atmosphere that we breathe. It is with the "why and the wherefore" of their existence that we are concerned. In looking for this, it will be necessary to consider the facts of the life history of these germs, and to try to discover how they have been and are influenced by their surrounding conditions. We find that the conditions favourable to the full vital activity of these germs are a moderate temperature, moisture, and a resting-place or nidus in some organic matter whose chemical constitution enables it to afford the pabulum necessary for the maintenance of their existence. On the other hand, the influences antagonistic to their well-being are excessive heat or cold, the action of certain chemical bodies, and a condition of dryness. The last is certainly prejudicial, as it seems to hinder their full vital activity. At the same time it cannot be considered absolutely obnoxious, as it is the means which favours their locomotion in the atmosphere. Putting aside, for the meanwhile, the thermometric and atmospheric conditions, we shall see that the condition which most concerns us is that of a favourable nidus. A favourable nidus is one in which the germ is enabled to carry on its full vital functions, and to propagate its kind. It is therefore manifest that the constitution of the nidus must be free from elements antagonistic to such vital functions. It must not be too hot, or too cold, or too dry, and its chemical constitution must be favorable. Experiment has proved that oxygen in excess is deleterious to these organisms; its absence, entire or partial, will then be one of the requisites in this chemical constitution of the nidus. Is not such nidus best found in decaying or degenerating animal tissue? Where there is full vital activity in any animal tissue, the blood which nourishes it keeps it duly supplied with oxygen. In healthy tissue, then, we have a condition unfavourable; but when from some cause the nutrition of the tissue is interfered with and a condition of degeneration is induced, this antagonistic element is removed or at least diminished, and the tissue affords the nidus favourable to the vital phenomena of the germs. These vital phenomena are perhaps best studied in the analogous case of the spores of yeast (torula cerevisiæ). When this, which is to all intents and purposes a germ, is placed in favourable circumstances, its activity commences, it rapidly multiplies and gives rise to changes in the surrounding material. In this case we call the process "fermentation." A germ, bacillus, bacterion, or vibrio, when placed in relation to tissue which affords a favourable nidus, assumes its full vital activity; it multiplies and gives rise to changes in the tissue with which it is in contact. These changes we call "inflammation." In fact, it would appear that these germs in one sense fulfil the part of nature's scavengers, and by setting up inflammatory changes in degenerate tissues lead to their removal. Be this as it may, the diseases to which the germs give rise are all more or less of an inflammatory nature.

Thus, then, it would seem that one of the chief vital functions of these germs is to excite an inflammatory process in degenerate tissue. Is it not conceivable that germs may have existed, or even do still exist now, whose function is strictly limited to action on degenerate tissue? That this may perhaps have been the limit strictly assigned to them? Let us suppose this to be the case, and see how from this limited condition, germs have acquired power to overstep these limits, and thus to give rise to the protean aspects of disease that we now meet with. What has caused variation in the animal world but the influences of surrounding circumstances? In the relationship of the germs and the degenerate tissue, it is plain that in one sense the germs are the active, and the tissue the passive, elements. But looked at from the tissue point of view, it will also appear that this passive condition possesses considerable indirect influence on the germs, that, indeed, "passive" is hardly the word to express the action which must largely modify their constitution. It would be impossible for the germs to live, to grow, to multiply on a certain tissue without becoming imbued with certain characteristics of that tissue. Hence a difference, a variation, between the parent germs and their offspring.

Now, the one characteristic of the tissue which most strikes our attention is its degeneracy, and this degeneracy must exert its influence on the organisms which depend upon it for existence, so that in the thus derived organisms we have the germ vitality and function, *plus* a certain amount of degenerate tissue characteristic. Germs thus modified and brought into contact with tissue of the same kind, though less degenerate, will, in virtue of this constitutional modification, stand a better chance of establishment thereon, at the same time adding to the degenerate condition with which they meet in the new tissue the characteristics of the degeneracy of tissue they have left. The effects thus produced will be more acute, the constitution of the germs further modified, and their power increased. Hence it is possible to conceive that if by any chance a condition of tissue which could be called perfectly healthy was to be anywhere met with, even this tissue might in time become subject to the influence of these organisms. Of course tissues may be more or less susceptible to their influence, more or less healthy, but it is more than doubtful whether it can be positively said of any one tissue that it is absolutely healthy, any more than it can be said of the individual man or woman. It is therefore possible to conceive that at some time or other there has existed only one kind of germ, that variations from this one type have arisen in consequence of the modification wrought upon different individuals by their chance falling upon this or that degenerate tissue. Variation must lead to specialisation, and finally we find diseases, all dependent upon the action of germs, as different from one another as one species of animal differs from another.

But there is another direction in which these germs must have been modified fully to account for the differences we now see. Germs may still exist which have only the power of exciting a simple inflammation in any degenerate tissue. Others, a step more advanced, are found, whose action is more potent, which have attractions for the one special tissue in which they have been bred; whilst others are capable of exciting the special form of inflammation in which they have had their origin, in tissues various in structure and composition. This power or, rather, increase of power—in other words, further variation in constitution—thus displayed is only to be accounted for by the supposition that its acquisition is secondary to the act of establishment, and that it is brought about by means of the blood itself receiving some of the germs and conveying them to some other tissue, on which, in virtue of its degeneracy, and possibly of a further modification, they have themselves received from the blood, they are enabled to effect a settlement. It must also be remembered that their modification, which enables them to select a tissue for their primary and more virulent action, does not deprive them of their original power of attacking degenerate tissue. It is simply an additional power, rendering them more potent when brought into contact with tissue possessing certain characteristics. These characteristics of the tissue originally attacked may determine the character of the action of the germs on other tissues, and thus enable us to recognise a relationship in the morbid influences at work in different tissue—as, for example, in syphilitic disease. If it is a fact that the tissue originally attacked modifies the constitution of the germs, it is surely more reasonable to suppose that the special characteristics thus impressed upon the germs are those which give the family likeness to the descendants of these germs, rather than to suppose that this morbid family likeness exists in the germs before ever they have been brought into contact with any form of degenerate tissue. In other words, may not a bacterion, pure and simple, by being brought into contact with some form of degenerate tissue, acquire or give rise to other bacteria which possess certain character-

istics which we recognise as being those of special disease, and that those characteristics enable them to excite a similar form of disease in the new nidus? It is also conceivable that as different diseases are more or less widespread or of older standing, so the germs given off from tissues affected by these diseases will have more and more power of affecting tissues less and less degenerate, even to the point of a possible condition of actual health. So, for example, the germs of scarlet fever or measles have actually acquired great power over the tissue which they primarily affect; whereas in the case of tuberculosis it is more than doubtful whether the actual presence of a tubercular condition of degeneration in the tissue, to a definite extent, is not necessary before the germs can find a suitable nidus in that tissue. Of course, germs derived from a tubercular origin will have more influence over tissue which is not so much affected than germs which have not such tubercular origin. It is, in fact, simply a matter of degree of degeneracy. May it not be this which enables persons free from tubercular taint to brave the assaults of germs be they ever so virulent?

The above are only one or two examples showing the different powers possessed by germs derived from the different forms of disease. The list of examples might be almost indefinitely prolonged. But the result would only be to show that different diseases have different powers of affecting the animal body, a fact already well known. It is the design of this paper to show that possibly these powers have been acquired by the action of some form of natural selection, here propositionally called "*tissue selection*," on the germs which inhabit the air we breathe and the water we drink; such action in the course of long ages having given rise to germs possessing special powers, and being now apparently unrelated to each other in any way. The intermediate steps between a simple germ and such a highly modified one, as, for instance, the variolous or tubercular germ, may be difficult to trace, for as we at present see these germs it is as though we were looking at a picture or photograph of a family tree in which the greater part of the trunk and larger branches had become obliterated, having only the terminal twigs visible, with no apparent connexion between them.

Holloway-road, N.

TWENTY-FIVE CASES OF

ABDOMINAL SECTION IN THE BRISTOL ROYAL INFIRMARY.

BY J. GREIG SMITH, M.A., F.R.S.E.,

FOLLOWING the good example of Dr. Malins, of the Birmingham General Hospital, and hoping to add something to the encouragement he has given to the performance of abdominal section in large public hospitals, I herewith put briefly on record my first series of cases operated on in the Bristol Royal Infirmary. I purposely exclude cases done in private. They are as follows: Ovarian cystoma, 17; solid growths of ovaries, 2; pyosalpinx, 2; hæmosalpinx, 1; exploratory, 3. A prolapsed, adherent, and diseased ovary successfully removed through the vagina is not included.

Among cases of cystic disease is included one where the tumour was mixed dermoid and cystic. In three cases the second ovaries were large enough to be reckoned as separate tumours; in five more the second ovary was removed because of incipient disease.

Of the cases of solid growth one was a pure fibroma of the ovary, measuring seven by eight inches in its diameters; in the other not only were both ovaries changed into solid growths, each about a pound in weight, but both Fallopian tubes were distended with a fluid fatty material, crowded with crystals of cholesterine.

One of the cases of pyosalpinx was the worst of the series. The patient had been very ill for two months; and when I saw her she was in a low typhoid condition, with high evening temperature (103°) and rapid pulse (120). She had also chronic bronchitis, with constant cough, and some fluid in the right pleura. The tumour was very thick-walled, rotten, almost gangrenous in parts, and, it need scarcely be added, adherent all over, more particularly to the bladder, uterus, and rectum. It contained about eight pints of highly offensive pus. There was free bleeding from innumerable points, which was checked by pressure of sponges. Part of the cyst wall, firmly adherent over the iliac vessels, was surrounded with a ligature and left behind. The operation had to be hurriedly concluded (within the hour), as the patient was near dying on the table. The treatment adopted was the following:—Nutrient peptonised enemata, drainage, and daily syringing of the abdomen so long as the discharges continued putrid. The ligatured portion came away through the wound as a slough, large enough to fill a three-ounce bottle. The patient recovered and went home, but now, eight months since the operation, there exists a sinus in the abdominal parietes, which is gradually closing.

Of the exploratory operations in one case the tumour was found to be malignant and to have invaded the peritoneum; the patient went home after a month and lived for nearly a year. A second was found to be encysted peritonitis from miliary tuberculosis. She recovered well from the operation, and died in nine months of her disease. The third was found, as was suspected, to be one of movable kidney, which was fixed.

Of these cases all recovered save one, and here the cause of death was volvulus. The patient was a broken-down woman of fifty-three, a cripple, with her joints all distorted from chronic rheumatic arthritis. The operation was not peculiarly difficult, and she appeared to be out of danger, when, on the fifth day, violent vomiting set in, which became stercoraceous in the end, and killed her in twenty-four hours. At the post-mortem examination a kink in the bowel, which was very dark and congested for a foot of its length above it, explained what, perhaps, ought to have been diagnosed during life. The rapidity with which she succumbed was easily explained by her general feebleness.

In all these cases Listerism was observed in its fullest details, even to catgut (with two or three exceptions) for the pedicle.

The operations are done in the general operating theatre, and no restriction whatever is put on students or visitors who may care to be present. For a week or ten days after operation the patient is kept isolated in a small ward; thereafter she is returned to the general ward. I may add that the infirmary building is a century old, that it stands in a low-lying, poor neighbourhood, and that its wards, affording less than eight hundred cubic feet to each patient, are always full, often overcrowded.

Clifton.

TREATMENT OF SEPTICÆMIA BY AMMONIA AND CHLORATE OF POTASH.

BY MAITLAND COFFIN, F.R.C.P. EDIN.,
PHYSICIAN ACCOUCHEUR AND TEACHER OF OBSTETRICS IN ST. JOHN'S HOUSE MATERNITY HOME AND TRAINING SCHOOL FOR MIDWIVES.

ON October 9th I was sent for to see Mr. T——. I found him very ill with erysipelas, and waited on by his wife, who was expecting her confinement every day. On the 14th I delivered her of a still-born female child, which had evidently been dead for a considerable time. Two hours after, I took her temperature; it was 100·4°, and fearing septicæmia, I gave her (having found it of use in other cases of blood-poisoning) large doses of ammonia and chlorate of potash; ordered carbolic acid (1 in 40) to be kept boiling in the room day and night, and the uterus to be syringed with Condy's fluid and water three times a day. The temperature went steadily up until the fourth day, when it reached 105·4°. The patient complained of pain in the throat and great difficulty in swallowing. The temperature kept from 105° to 105·2° until the morning of the tenth day, when it steadily declined until the evening of the twelfth day; then it went up a degree. The patient passed a large quantity of fetid discharge. I ordered the uterus to be syringed every three hours; she continued to improve, and at the end of one month I allowed her to come downstairs. On the sixth day she had some septicæmic spots, which disappeared on the thirteenth day, and throat symptoms on the ninth day. With regard to temperature, for six days and a half it was over 105°, for nine days over 103°, and for eleven days over 102°.

The treatment of puerperal fever by constitutional remedies, as distinguished from those which act locally and antiseptically, is one of great interest and importance.

Those principles which can be applied in the latter case with undoubtedly good effect are not easily carried out in the former. We can conceive that even after local septic activity is arrested, the blood and tissues of remote organs may be extensively infected; and we may naturally inquire whether there are any agents which, administered internally, will arrest the general septic processes, such as the cutaneous changes, which were well-marked in this case, or the analogous processes which we know by pathology are at work in the lungs, kidneys, and other organs. The agents which I employed in this instance have been used by me in similar cases with success, and I venture to think that the facts are worthy of being recorded, though the explanation of the *modus operandi* may not be very distinct. It may be possible that the agents used produced a change in the condition of the blood, which, though very slight, was sufficient to arrest the vitality of the bacteria or micrococci which characterise puerperal infection. To offer any suggestion, however, of this kind without some proof of its probability would be reprehensible, therefore I will conclude without further remarks.

Baron's Court, West Kensington, S.W.

ST. MARYLEBONE INFIRMARY, NOTTING-HILL.

A CASE OF ULCERATIVE ENDOCARDITIS.

(Under the care of Mr. HERBERT LARDER.)

THE following case of ulcerative endocarditis, for which we are indebted to Mr. Larder, is one of a class of cases interesting to all—from the difficulty with which they are diagnosed, from the multiple changes which occur during their course, from the etiology, and also from the resistance to treatment which they exhibit. It is possible that cases have recovered; these must have been of slight severity, and the diagnosis of necessity very doubtful. We would refer to the remarks of Mr. Larder, which are appended to the case.

Albert M——, aged forty, a labourer, was admitted on May 7th, 1884. There was no family or personal history of any importance, and no definite account of rheumatic fever. He was accustomed to work in drains, and attributed his illness to having caught cold a month ago whilst at work in the rain. A few days afterwards he had a severe attack of shivering, which recurred on several occasions up to the time of admission. He stated that he had felt much worse since May 4th, when he took to bed; he suffered from headache, thirst, loss of appetite, and general malaise. He had noticed swelling of the eyelids and face on rising in the morning, and that his urine was scanty and very dark in colour.

On admission his state was as follows:—He was a well-nourished, muscular man; skin dry; no œdema of face or extremities; tongue moist and furred. Temperature 103°. He was lying on his back, and appeared to be very ill; he complained of cough, headache, and thirst. There was some slight loss of resonance on percussion posteriorly at the base of the left lung. There were well-marked signs of cardiac hypertrophy and a loud systolic murmur over the entire cardiac area, but heard loudest over the aortic cartilage. There was no distension or tenderness of the abdomen and no rash.

May 8th.—The patient was very sick last evening, and his temperature ran up to 105·6°. Slept well during the night; bowels opened three times, motions light in colour, and closely resembling those seen in enteric fever; urine acid, sp. gr. 1030, it contained blood, and about one-half albumen. There are numerous spots of extravasation over the trunk and lower extremities; no distension or tenderness of abdomen; tongue red and dry; skin moist.

10th.—Patient very restless; he complains of pain in both shoulders, and cries out on being moved. No swelling or redness of joints. He is lying on his back, sweating profusely, and appears very prostrate. The facial muscles are in a state of constant twitching, and there is marked subsultus tendinum at the wrist. The breath is offensive, the tongue dry and brown, and sordes on the teeth and lips. The face and conjunctivæ are suffused. He lies in a torpid, dreamy condition, with muttering delirium, but is easily roused when spoken to. The diarrhœa continues, and the motions are of the same character.

11th.—The patient remained in much the same state until 3 P.M., when the prostration increased. About 9 P.M. he had an epileptiform attack lasting a few minutes, with general twitching of muscles and frothing at the mouth. When seen immediately afterwards he was lying on his back, breathing stertorously and sweating profusely; the extremities were cold and pupils dilated, but acted to light and accommodation. He roused up when spoken to, and could answer questions, but immediately relapsed into his former condition. There was much difficulty in swallowing, but no pain; pulse extremely small and feeble. He rallied considerably under the influence of brandy, hot bottles, and blankets, but gradually sank and died at 4 A.M. on May 12th. The treatment adopted was mainly stimulants, with beef-tea, eggs, &c.

The case was considered to be one of ulcerative endocarditis on the following grounds—viz., on account of the increasing cardiac murmur, petechial eruption, renal symptoms and irregular pyrexia, with the absence of abdominal symptoms, in proportion to the duration and progress of the attack.

	Temperature.	Pulse.	Respiration.

Necropsy, fifty-nine hours after death.—The body was well nourished; cadaveric rigidity very well marked in the lower extremities, but passing off in the upper. Post-mortem congestion on dependent surfaces and the lymphatics of arms mapped out. There were numerous ecchymotic patches over the trunk and lower extremities, which had been present during life. There was no swelling of the joints, but some sign of commencing ulceration over the left olecranon. Brain weighed forty-six ounces; dura mater normal, subarachnoid fluid increased in quantity, superficial vessels distended, punctæ well marked, brain substance soft. There was about half an ounce of semi-purulent fluid in each lateral ventricle. The pia mater appeared somewhat thickened and adherent to brain substance. The parietal peritoneum was apparently normal, but the small intestines were marked by numerous patches varying in colour from pink to a dark-claret colour. There was no sign of ulceration in the bowel. The spleen weighed ten ounces; it was dark in colour and extremely soft. The liver weighed fifty-six ounces; it was very pale and easily broken down on pressure by the finger. The left kidney weighed nine ounces, surface smooth, capsule easily stripped off, substance generally pale except at the lower part, which was of a dark-claret colour. The right kidney weighed three ounces and a half; it was marked by numerous dark-coloured spots of infarction, but otherwise pale in colour. The posterior wall of the stomach was of a dark-purple colour in its upper two-thirds. Bladder and rectum appeared normal. Chest: There were some slight pleural adhesions on the left side, and the right pleural cavity contained three or four ounces of blood-stained fluid. On opening the pericardium the heart appeared unusually pale in colour; the pericardium was apparently normal, and contained a very small quantity of clear serum. The right auricle contained a firm, yellow, non-adherent clot, moulded to the cavity and fibrinous in character. The right ventricle was dilated, and contained some similar clots adherent to the valves. The semilunar valves were slightly swollen, but there was no trace of vegetation. The left auricle contained a small firm yellow non-adherent clot. The left ventricle was hypertrophied, its muscular wall firm and pale in colour, and the

endocardium thickened and somewhat opaque. The curtains of the mitral valve were thickened, opaque, and marked by small vegetations. The aortic valve also appeared thickened and opaque. There was well-marked ulcerative disease of the ventricular surface of the aortic valves. On the ventricular aspect of each aortic cusp there was a firm nodule of fibrin, the size of a small Spanish nut, and firmly adherent to the surface of the ulcers. There was also a firm yellow clot adherent to the anterior cusp, and extending about three inches along the aorta. Ante mortem there was a thin firm string of fibrin extending into each coronary artery. The lining of the aorta was deeply blood-stained, but there was no sign of atheroma of the vessel. The endocardium and substance of the heart for about two inches below the valve were of a dark-purple colour. The heart weighed fifteen ounces. The right lung weighed twenty-eight ounces and a half and the left thirty ounces. The bases were congested, and the substance generally œdematous.

Remarks.—The case just related seems worthy of publication—first, on account of the disease being somewhat rare, and yet probably frequently overlooked. Secondly, on account of the difficulty of diagnosis which instances of the malady often present; and yet due recognition is of importance not only for our private satisfaction and as a basis for correct prognosis, but because timely and energetic treatment might mitigate the severity of the complaint, and perhaps save life. Thirdly, on account of its pathological obscurity; for though it is almost certainly a member of the class of septic fevers, yet on some grounds it seems to have quite a separate mode of causation. And if it be specific, it would be of interest to learn how closely it is allied to other members of the same group. In the first place, it must be noted that while a full description has been omitted in nearly all our text-books of medicine, even up to the latest editions, there is a good account to be found by Rosenstein in Ziemssen's Cyclopædia (vol. vi.), which contains almost as much as is known in the matter. In that article, after analysis of a number of cases, they are classified, according as one or another set of features predominate, into two varieties—pyæmic and typhoid. The case here related, like many others, was a mixture of the two types, in the earlier part of its course, at any rate, having close resemblance to pyæmia, while its nature towards the end strongly suggested typhoid fever. After the man was admitted into the infirmary the history contained a fact of great importance in forming a diagnosis—viz., that as the disease invaded him he had repeated severe rigors. Now, this would almost for certain exclude typhoid fever, and, putting ague out of the question, as well as bladder and suppurative renal disease, give assurance of some sort of pyæmia. Then also the presence of an increasing cardiac murmur, of a petechial rash, albuminuria in a high degree, and later hæmaturia (suggesting a renal embolus) were almost convincing evidence of ulcerative endocarditis; and the absence of an abdominal rash, &c., carried one's thoughts further from typhoid fever. In all cases of this disease the heart should be carefully examined, both during life and after death, to determine how much of the disease is recent and how much is old and chronic; for it is recent disease that constitutes the specific character of the malady and gives it its name, and is the source of certain complications almost invariably present. Here there was probably old disease, for the enlarged cardiac area showed the heart to be dilated and hypertrophied; and it is a fact that all or almost all cases occur in subjects of valvular disease from former endocarditis, generally of course due to previous acute rheumatism. Now, is this condition necessary to the development of ulcerative endocarditis, so that the latter may be excited on exposure to infection; or may exposure to specific infection induce it though the valves be healthy, so that it may be regarded as the proper lesion of an acute specific fever? Or, again, is it possible that an existing valvular disease may be a sufficient cause of an ulcerative process and its malignant consequences—i.e., may an acute attack of endocarditis, occurring, for instance, in a fresh attack of rheumatic fever, supervening on a chronic inflammation, go on to ulceration of the endocardium, and so engender a literal pyæmia, the blood in the heart becoming mixed with unhealthy pus, and thus produce embolism of the organs? This view seems unlikely, but is not impossible. The idea most generally adopted, and perhaps most probable, whether or not living organisms, so-called micrococci, are answerable for this and other septic diseases, is that it is an acute specific fever belonging to the miasmatic group—viz., diphtheria, scarlet fever, &c., perhaps attacking the heart as a "locus minoris resistentia" in consequence of prior disease. But if so, why is not endocardial ulceration more common in these complaints? Is a distinct poison requisite in addition, or only the presence of exceptional bodily conditions? Or if the endocardial ulceration is a sort of metastatic inflammation, why is it not more commonly met with in surgical pyæmia? The man's statement that he had caught his illness while exposed at work in drains gives favour to the miasmatic theory of causation. But it has been asserted to occur in some cases as a complication of rheumatic fever, and in this case there were articular symptoms; but the point was not settled at the post-mortem examination whether the affection of the joints was rheumatic or, as seems more likely, pyæmic. As to the nature of the blood-poisoning, nothing definite is yet known of the micro-parasitic origin of the disease.

Treatment.—Some good might be done, following Armstrong's plan of treating puerperal fever, by a large dose of calomel in the early stage, followed by salines. Quinine and alcohol, freely given, should be reserved for the later stages.

YORK COUNTY HOSPITAL.

A CASE OF CHARCOT'S JOINT DISEASE.

(Under the care of Mr. JALLAND.)

MR. JALLAND'S case of Charcot's joint disease will be found specially interesting when taken in connexion with the discussion which followed Mr. Morrant Baker's paper read before the Clinical Society. In the prolonged discussion which followed the reading of the paper, most of the principal authorities expressed their opinions on the nature of the disease. These are too numerous to permit of mention here, and we would refer our readers to THE LANCET (Nov. 22nd, Dec. 6th and 20th, 1884; and Jan. 3rd, 1885) for an account of the proceedings of the Society.

For the following notes we are indebted to Mr. A. Jefferson, house-surgeon:—

Eliz. C——, aged forty-eight, a widow, was admitted in May, 1884.

Family history.—No history of any nervous complaints in any member of her family.

Previous history.—Has had no children. Since her husband's death she has followed the occupation of a charwoman; she has got on fairly well, and has not suffered much privation. Until her present illness began she was always healthy.

Present illness.—This commenced eleven weeks ago. One afternoon she was scrubbing a floor, when suddenly she felt pain in her left hip; on trying to walk she found she was quite unable to get on her legs. She was conveyed home in a cab and put to bed, her neighbours looking after her. She did not send for a doctor, thinking it was simply rheumatism, and would go off again. Previous to this she had had no lancinating pains, did not stumble in the dark, nor had her sight at all deteriorated. She remained in bed about a fortnight, and then came downstairs. This she effected in a sitting position. She found she could get about her room by holding on to the furniture, but could not take a step without. By this time the pain had left the hip. Fresh symptoms were next developed—namely, pain and swelling in the left knee, both apparently rather extreme. After a few days these somewhat subsided. She was now medically attended, and an exacerbation of the knee symptoms occurring, she was recommended to apply for admission to the hospital.

Condition on admission.—The patient complains of pain and sleeplessness caused by a "tumour" of her left knee. She looks fairly well nourished but is evidently suffering a good deal. On examining the knee it is found to be much enlarged, there being an extreme amount of synovial fluid, while through the fluid firm enlargements of the head of the tibia can be felt. The foot and leg below the knee are œdematous and there is distinct enlargement of the superficial veins over the joint. The condition of things was in fact compatible with new growth in the head of the tibia with secondary synovial irritation and effusion. The limb was placed on a McIntyre's splint and a Martin's bandage applied from the toes to above the knee. There was some pyrexia at night, the temperature rising to 101° and 102°. At first the pain continued severe and kept her

awake. There was nothing, however, in the form of lightning pains, all unpleasant sensations being localised to the joint. A week after her admission the effusion had disappeared almost entirely and the limb was taken off the splint; in doing this sudden partial dislocation of the tibia and fibula backwards into the popliteal space took place; this was accompanied by much grating and was easily reduced. Subsequently this partial dislocation was frequently induced purposely, but it never caused the patient the slightest pain or inconvenience. The enlargement of the head of the tibia was now found to be due to osteophytic outgrowths; these were not very irregular, but formed a kind of collar round the head of the bone. The history of the illness, as already noticed, was now elicited, the patient previously having said nothing about her rheumatic hip. This hip on examination was found to be dislocated on to the dorsum of the ilium by simple rotation. This dislocation was easily reduced, the bone slipping into its socket with much grating; dislocation and reduction could be easily effected, and gave rise to no pain whatever. On making further examination, a hard, bony, smooth mass, osteophytic, could be felt growing from the pelvis in the right iliac region; this was about the size of an orange, and its surface was rounded; another mass of osteophytes could be felt running down the shaft of the femur, covering about the extent and situation of the upper third of the linea aspera. This chain was a very prominent one. No other joint or bone affection could be discovered. On testing for reflexes, plantar and patellar reflex were in both limbs absent. Muscular power seemed quite undiminished in the right leg. The condition of the knee and hip on the left side made it difficult to test the muscularity of that limb; but the patient was quite able to move it about. Sensation in the left limb was somewhat diminished as compared with the right. The pupils were dilated but did not act to light. Nothing was noticeable in the optic discs. After staying in the hospital about a month the patient was discharged. By this time the fluid in the knee had entirely disappeared, as had also the œdema of the foot and leg on that side; the pain had also gone, and there was no longer pyrexia. No other symptoms, save those already mentioned, appeared during her stay in the hospital. Unfortunately, after leaving she changed her address; endeavour was made to find her, but without success.

Remarks.—This case illustrates a point laid stress on by M. Charcot—namely, that the arthropathy appears, as a rule, very early in the disease, before incoördination. The suddenness of the onset and the insidious nature of the hip arthropathy were very remarkable, as the patient declared that until the afternoon on which, when scrubbing, she felt the pain in her hip she had felt perfectly well; for we can only conclude that the sudden pain and inability to stand or walk which came on thus rapidly were due to dislocation of the hip. Another remarkable point was absence of any atrophic change in the optic disc. This of course is very different from what one would expect to find, disc changes being generally the first objective signs of locomotor ataxy. It is also curious that we have an entire absence of lightning pains, the presence of which generally, according to Charcot, is the only exciting symptom of the complaint. Charcot also says that this arthropathy is not commonly accompanied by fever, but in this case the temperature at night for some time went up to 101° and 102°.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Discussion on the Tubercle Bacillus and on the Pathology of Phthisis.

An ordinary meeting of this Society was held on Tuesday last, Dr. George Johnson, F.R.S., President, in the chair. At the commencement of the evening a special ballot was taken to decide whether Dr. Herbert Tibbits should be re-elected as a Fellow of the Society. At the close of the ballot the President declared Dr. Tibbits to be not elected. The discussion on Dr. Kidd's paper was adjourned, and a special meeting for the adjournment was fixed for Wednesday, Jan. 21st, at 8.30 P.M. An excellent demonstration of the bacilli of tubercle and of their methods of cultivation was given by Mr. Watson Cheyne, and Dr. Kidd's valuable specimens were also on view.

Dr. HERMANN WEBER had noticed that but few of the bacilli were within the cells; for the majority of the bacilli were outside the cells and in the detritus of the tubercle. Were the specimens shown by Dr. Kidd taken from a late period of the disease in which the cells had perished and left the bacilli scattered about? An observer had recorded in the *Deutsch. Archiv* cases in which sections showed four or five bacilli in a great many ordinary cells of tubercle. Allusion was next made to the struggle which Metschinkoff had described between bacilli and white blood-corpuscles in the daphnia, as quoted by Mr. Bland Sutton. Had anyone observed the same process in warm-blooded animals? The greater or less vigour of the cells of different individuals might account for the varying susceptibility to tubercular infection. The pathology of apical consolidation was discussed; some cases which were simple at the outset probably became "bacillary," and led to the usual changes of tubercular phthisis.

Dr. GREEN said that Dr. Kidd's paper is an addition to the continuously increasing accumulation of facts which tend to show that the bacillus of tubercle is present in all those pulmonary lesions which we regard as phthisical, whilst it is absent in those which do not come within the category of phthisis; and in such a question as this we want facts rather than opinions. He would ask, with Sir Andrew, what Dr. Kidd meant by phthisis. Definitions of disease are admittedly difficult, but he might venture to define clinical pulmonary phthisis as including all cases of pulmonary disease which possess the three following characteristics:—(1) Lung consolidation which is usually more or less apical in its distribution; (2) lung consolidation some of which tends to undergo softening and disintegration; and (3) lung consolidation which possesses infective properties, and thus tends to spread. Such a definition excludes some forms of chronic lung disease which have occasionally been included in the phthisical category: chronic basic pneumonia with bronchiectasis; the indurative diseases of the lung due to irritating particles; the inflammatory disorganisation of the lung which results from pressure on a bronchus, and the pulmonary lesions which are distinctly syphilitic. This clinical and pathological distinction between phthisical and non-phthisical forms of lung disease is, he thought, justifiable, apart from any question of bacilli. How far is it in accord with Koch's discovery? He believed that it was in complete harmony with it. The unity of phthisis seemed to be established by the observations of those who had worked on the subject. He next inquired into the question, Are we familiar with apex consolidations which are non-tubercular? In some cases of disease at one apex, where there was no evidence of softening or disintegration, it is difficult to say whether they are tubercular or not. If they are simple are they specially liable to become tuberculous? Can we accurately speak of a pretubercular stage of phthisis? He confessed that almost insuperable difficulties seemed to surround an answer to these questions. The subject may be viewed from the standpoint of clinical history or from that of bacilli. If frequent and careful examination failed to discover bacilli, may we conclude positively on their absence? In his experience it is rare to meet with apical consolidation in which tubercle bacilli are absent. Are we justified in saying that the case is non-tuberculous if bacilli are not detected? He was afraid yet to express an opinion on this point. With regard to the clinical history, we might have termination in resolution or breaking down and progression, which he would regard as tubercular in all cases. If the symptoms disappear and the signs clear up, is it to be regarded as evidence that the case was non-tuberculous? Naturally the ultimate history would be wanting. He, for one, believed in the curability of the tubercular process, and he should doubt the existence of non-tuberculous apex consolidations. He questioned the existence of a recognisable pretubercular consolidation. Referring to scientific criticism of Koch's discovery, he considered that the question was one for experimental pathologists to investigate, and so far experimental pathology confirmed Koch's and Watson Cheyne's observations. The acceptance of the bacillary origin of tubercle in no way involves any mutilation of previous existing notions, and he ventured to say that pathology had long been tending towards the position to which these latest doctrines pointed.

Dr. WILSON FOX said that but comparatively few members of the Society could be in a position to discuss the essential

question which Dr. Kidd's paper raised. The study of the mode of generation and of propagation of the different varieties of bacteridia was one requiring special skill and training. In nearly every form of tubercle, and in pus proceeding from tubercle, the characteristic bacteridia had been found, and so far the evidence in favour of Koch's views was strongly confirmatory. We were much indebted to Dr. Kidd for having subjected this question to the most careful and painstaking research. The point was no doubt too important to pass over merely on the *ipse dixit* of one man, however great. About fifteen or sixteen years ago Dr. Hermann Weber, in speaking of the effects of cold climates on phthisis, had suggested the notion of the dependence of the disease on germs, and this paper of Dr. Weber antedated Villemin's experiments. The failure to find bacteridia in some cases would not destroy the phthisical nature of the disease, for one would not expect to find the active agent in all cases. Leyden had pointed out that the fallacies of the histology of the sputa in relation to the bacilli were more numerous than surrounded the older methods of investigation. Tubercle was an inoculable disease, and almost nothing else is so inoculable as it. The experiments of Cheyne and Dawson Williams proved that tuberculosis could only be obtained by the inoculation of specific material. Diseases which were due to bacteridia were for the most part contagious, but it would be a grave step to assert that tubercle also was contagious. Inhalations of pulverised tubercle in a densely crowded atmosphere gave experimental proof of the contagiousness of tubercle, but the evidence of the proof that tubercle was contagious in man was of the most difficult kind. Dr. Reginald Thompson had concluded from experience at the Consumption Hospital that about one case in a thousand had possibly received its disease from contagion. The collective investigation under the direction of the late Dr. Burney Yeo gave out of 1078 returns 262 as possible cases of contagion. Dr. Fox was surprised that so many gentlemen had returned it in the negative; of the whole number of cases there were but twenty in which there was no personal relationship between the cases concerned, or in which they had not lived under the same conditions. Bowditch, Buchanan, and Simon had shown that many unhealthy conditions in life are followed by the development of phthisis. We ought to feel indebted to Dr. Creighton for his criticism of Koch's method. Although the evidence in favour of Koch's views was so strong, yet, looking to the constant change in our views of phthisis, and seeing how the pathology of tuberculosis has biennially, triennially, or quinquennially been swayed by histological dogmata, it would be well if we waited before definitely accepting all that the new views implied. Who could tell but that in a few years we should hear expressions in terms which at present we cannot foreshadow? It should be remembered that the bacteridia of tubercle depended for their detection on one of the most uncertain of chemical agents, an aniline dye.

Dr. MOXON said he hesitated very much in venturing before the Society. The question before us was the most important question which had been placed before this Society during the present century. He had long held the view that all phthisis was the same disease, and had done so from anatomical considerations; he had long observed that tubercle was always spherical, and thought there must be some reason for this; he had compared them to fairy rings; in masses of tuberculous growth the periphery was living and the centre dead. He did not mean much by the term fairy ring; it was almost poetical. He believed that we had now revealed the cause of the factor which makes phthisis one and the same thing. Twelve years ago this very question was raised at another Society, and Dr. Wilson Fox had shown that of all the kinds of phthisis the histology was identical; though, as he understood him, Dr. Fox hesitated to allow that, pathologically also, the different kinds were due to one and the same process. From a constant and close system of observation, in which the purulent expectoration was carefully examined, he had come to believe that Koch's view was right. In cases of capillary bronchitis the sputa contained no baccili; and in three cases of gangrenous lung which ran a chronic course the sputa revealed no bacillus. Not always in every case of phthisis will bacillus be found. The life of a tubercle is not the history of a phthisic. Three months was about the duration of the life of a tubercle; whereas that of a phthisic may be twenty years. Probably fibroid phthisis must be four or five years old at least. He had come to the conclusion that phthisis was a compendium of every disease in pulmonary pathology excluding cancer and including embolism. He next spoke of the fact that pregnancy disfavours phthisis, as did also heart disease, and, in fact, all venous conditions. Hence it was that tubercle did not exist, as a rule, in the region of the Pacchionian bodies, and that they never occurred in the liver. When we considered the delicate favourable conditions required for the growth of the bacilli, we could explain much. The life of a parasite is not so easy as it seems at first sight to be; even the aphis of a rose does not live in a westerly wind; and so, though we might catch tubercle bacilli at every moment, yet a favourable soil might be wanting. A good sister in the ward of a hospital, characterised for great practical ability (Miss Pollock), had conducted a series of observations, and had proved herself extremely skilful in the preparation of specimens. It would be well if we had some central authority to act as a referee, to whom specimens might be sent by busy practitioners, and where they might be hall-marked if the specimen contained bacilli. It had been said that small-pox devours in the blood a substance necessary for its growth, and after this material had been used up the individual was unable to again go through that process. He suggested that after vaccination of a sheep with the modified virus of charbon, in order to prove the point, it would be possible to kill that sheep and make an extract of it to see if the extract would afford any food for the growth of the charbon bacillus. With regard to the use of antiseptic agents in phthisis, he said that he had soaked a patient with iodoform, and though the right lung only was affected, yet the left lung burst into the most violent signs of consumption under this treatment. The vitality of bacilli probably depended on the fact that they were individual particles of protoplasm, whereas in a complex organism the parts were sustained one by another, and there existed a coördination of action.

Mr. WATSON CHEYNE said that with regard to the bacilli he had not much to add to what he had already recorded in his published work. The exact relation of the bacillus to the tubercle itself was important. The epithelioid cells were perhaps the most important histological elements; their nuclei were larger and more granular and less deeply stained than other parts. It was in these epithelioid cells that tubercle bacilli had been found, and generally nowhere else. He had traced the development of these cells into giant cells, which were known to contain large quantities of carbon. In cases of fibroid phthisis one never finds them in fibrous tissue, but he used a low power first to detect epithelioid or caseating cells, and then the bacilli could be discovered. With regard to caseation, he was sceptical of the view that it was due to deprivation of blood. The epithelioid cell caseates, and may it not be the bacilli which cause caseation? How do they act in producing the changes? He thought it was a chemical action. (Photographs were shown in illustration; in one a dark mass of micrococci was seen in the centre, and around this a clear ring with no staining—dead tissues do not stain,—and round this a third ring of inflammatory cells.) It was easy to interpret these changes; the micrococci in the centre evolved a chemical poison, and, in a concentrated form, it had killed the tissue in the immediate vicinity, whereas further outside it merely acted injuriously on cells and excited inflammation. The course of events in phthisis was probably as follows: Some bacilli are inhaled by a predisposed person, or one in a fit state for the development of the bacilli. Then hypertrophy and multiplication of the epithelioid cells take place, a production of poisonous chemical substances occurs, and the cells succumb to the increasing amount of irritation; the giant-cells may ultimately overcome the bacilli; the inflammation that occurs around this centre aids in the spread of the process. The formation of this chemical poison probably accounts for some of the other symptoms, such as the fever and wasting of phthisis. With regard to the criticism of Koch's method by Dr. Creighton, he would attend to four points in the cultivation of the tubercle bacillus. He would not follow Dr. Creighton in the personal mode of questioning Koch's accuracy which had been adopted, for Koch did not require any defence from him. He should prove that Koch had not departed from the original principle of cultivation in dry media; that he had separated bacilli from tubercular matter; that in fluid media we have not a good method for cultivating bacilli. Koch had not departed from the original method of cultivation in solid media, for by this method it was possible to conduct pure cultivations through any number of generations. The accidental falling in of

micrococci from the air was more likely to happen and to vitiate cultivation in fluid media; whereas in the solid media the two organisms would grow together, and their distinction would be perfectly easy. If a micrococcus fell in from the air, it would only grow where it fell, and so the cultivations were pure. (Specimens of pure cultivations on solid media were handed round.) In the tubercle itself the bacilli were readily distinguished, and the problem was how to get and carry on the pure cultivation of bacilli, and in the method now used by Koch there was no departure whatever from the original principle. We could prove that the bacillus alone was present by its peculiar chemical reaction with the aniline dyes. It was necessary to use solid media, and coagulated blood serum answered the purpose best, as it had to be solid at ordinary temperatures. The method was as follows. A rabbit was inoculated with tubercle on the back, and six weeks later it was killed in a state of tuberculosis. Some prepared sterilised blood-serum should be at hand. The animal being killed, then wash the abdomen with 1 in 1000 solution of corrosive sublimate, and heat all knives, scissors, and forceps used in dissecting and excising portions of tubercle. Having inoculated a solid medium with the excised tubercle, the tubes are put in an incubator, and after eight or ten days a whitish dryish-looking substance, which breaks into bits, crust-like growths, form on the surface of the serum; if a particle of this crust-like material be inoculated on another test-tube containing the same solid medium the growth is much more luxuriant, for the reason that the bacilli are more perfectly distributed. (Specimens of the bacilli growing in coagulated blood serum were shown.) Speaking of these crusts, Mr. Cheyne said that it was easy to prove that they consisted of tubercle bacilli and nothing else, for by employing Ehrlich's method of first staining with fuchsin and afterwards with methylene blue, it was found that the crusts consisted of nothing else than bacilli, for not a patch or particle of blue was to be seen with an oil immersion lens; there was no other organism and no other material. As to growths in fluid media being better, he had worked for years with fluid media, and believed at last that he had found a medium more certain than any other, when he confessed that Koch's dry method had rendered all his work futile, and he had to become an adherent of the solid method. Long before Schiller's experiments he had worked with fluid media; he had inoculated various infusions with tubercle, and in no single instance did he obtain any development of the bacilli; the fluid remained perfectly clear. If a cheesy gland were used a slight development might take place. If the bacilli do not develop in fluid media, then Dr. Creighton's argument fell to the ground. Bacilli grow away from the tubercle, and so there was no tubercle after the very first generation, for the crusts of the first generation were nothing but bacilli. Moreover, if one rabbit be inoculated with tubercle and another with bacilli from the "crusts" alone, the latter would be far advanced in tuberculosis before the other showed much change. He did not object to criticism, but Dr. Creighton had totally misrepresented Koch.

Dr. WILSON FOX said that Dr. Moxon had misunderstood him, for he had all along believed in the pathological unity of phthisis. With regard to his remarks on Dr. Creighton's criticism of Koch's work, he confessed that he had not noticed that there was any imputation of want of faith.

CLINICAL SOCIETY OF LONDON.

Lesions of the Frontal Lobes.—Recurrent Hæmatemesis, with Urticaria.

THE annual general meeting of this Society was held on January 9th, Sir Andrew Clark, President, in the chair. The President announced that the following gentlemen had been elected to serve on the committee to inquire into the nature of the various specimens of Charcot's disease recently brought before the Society:—Sir James Paget, chairman; Mr. Morrant Baker, Dr. Dyce Duckworth, Mr. T. Smith, Mr. Warrington Haward, Dr. Barlow, Dr. Andrew, Dr. Buzzard.

Dr. HALE WHITE read a paper on Lesions of the Frontal Lobes. The first case brought forward was that of a woman, aged twenty-six, who was admitted into Guy's for severe headache. There was a history of injury to the head eight years previously. She had been ill a month with occasional loss of sight, and during this time she was twice sick, but her whole illness had been so slight, and she had been so well able to walk about and perform all the duties of life that neither her friends nor her doctor thought that anything serious was the matter with her. On admission the only symptom to be detected was optic neuritis, and she complained of nothing but intense headache. One day after she had been in the hospital about a month, being very tired with walking about all day, and having a severe headache, she went to bed early, and was soon after found dead in her bed. At the post-mortem examination a large glioma of the frontal lobe was discovered. It did not extend far enough back to implicate either the motor area or the island of Reil. The rest of the brain was absolutely healthy. The second case was that of a woman, aged thirty-one, who suffered from aortic disease; she also had paralysis of the left arm and leg, but there were many signs showing that this was not due to organic lesion, but was probably functional; this paralysis soon recovered, and the patient was well able to walk about the ward and use her hand. After she had been in about two months, whilst in the watercloset she had an epileptiform convulsion, was cyanosed, frothed at the mouth, and was insensible. On coming round she vomited excessively; in a few days she quite regained her former condition, but about two months afterwards her cardiac symptoms became worse, and she gradually sank and died. At the autopsy severe aortic and mitral disease were discovered with infarcts in the kidney and spleen; a black-coloured clot was found situated in the white matter of the right frontal lobe. It implicated slightly the gyrus fornicatus, but did not extend into the ventricles or affect the motor region of the brain. It was pointed out that the great interest of these cases lay in the paucity of the symptoms produced by the lesions of the frontal lobe, for in neither case were there any motor, sensory, or intellectual symptoms referable to the disease of the brain; in fact, in the second case the hæmorrhage was not even suspected, nor would the tumour with any certainty have been diagnosed in the first case but for the optic neuritis. Although the frontal lobes are generally looked upon as presiding over the intellectual faculties of the individual, from these and many other cases it is proved to be possible for one of them to be seriously influenced without any impairment of such faculties. The author enunciated it as a law that the later in the animal series or the life of the individual any faculties were developed, the more readily, in cases of injury of the brain, was some other part capable of taking on the work. Thus, motion of the leg and arm of one side, when destroyed by lesion of the opposite side of the brain, was slowly recoverable, because the faculty of motion had been so long formed as to become quite fixed in the motor areas on either side of the fissure of Rolando; whilst motions of the face as used in gestures, being later formed, were not so definitely fixed, and therefore either some bilaterally associated part near, or the sound side, was capable of taking on the duty of the injured part, and thus the face in ordinary hemiplegia recovered comparatively quickly. Coming to faculty for connecting words with signs, which was still more lately formed; here the uninjured side was quickly capable of taking up the function of the injured one; whilst in cases of lesion of the frontal lobe destroying functions so lately formed as the intellectual, the opposite side so quickly took up the work of the damaged side that no impairment was detected. The author was inclined to think that the recently acquired capabilities, such as the intellectual, were stored up on both sides of the brain; in the course of many generations these became more fixed to one side, so that then it would take some time for the functions of one side to be taken up by the other, whilst later functions were taken up at once by the sound side. The extent of injury in his first case seemed to negative the possibility of the bilaterally acting centre theory being true for intellectual faculties.—Dr. MOXON thought that it was not sufficiently recognised that people with brain tumours sometimes die suddenly. A consideration to which he had drawn attention in his Croonian Lectures, though it had been very much buried was nevertheless still believed in by him and was of great interest. The pneumogastric nerve, of all the cranial and spinal nerves, runs the shortest and straightest course from its origin to its escape from the dura mater. It forms, as it were, the central nerve of the whole system. Above it all nerves incline upwards or forwards to their exit; below it all incline more or less downwards. An anatomical feature of the fourth ventricle, which seems to be lost sight of, is the sort of lateral pouch which is stuffed very full of tufts of bloodvessels in the form of choroid plexus. This stuffed pouch reaches down and presses upon the pneumogastric nerve-roots, and an extra pressure from overfulness of this tuft may be an explanation of some

cases of sudden death from brain tumour.—Mr. VICTOR HORSLEY said that the absence of symptoms in Dr. White's interesting cases afforded a proof that in all psychical acts in which the attention is fully occupied both hemispheres are engaged, consequently that such ideas are bilaterally represented in the cerebral cortex. He believed that he has been able to prove this experimentally by the following method. If one attempts to draw simultaneously a triangle with one hand and a circle with the other, the result will invariably be that neither figure will be drawn correctly, both hands describing a fusion of the circle and triangle. Hence, he argued, the hemispheres are incapable of acting simultaneously when each is actuated by a separate idea upon which the attention is fully set. Supposing this view to be correct, it follows that since both hemispheres are occupied in any given idea, it would be stereotyped in both, and hence the destruction of one would not cause a loss of function obvious to untrained observers. Besides, tumours exert their destructive influence so very gradually as to readily admit of the opposite hemisphere rapidly assuming the lost function. A further point of interest lies in the possible function of the frontal lobes. In all cases of severe destructive lesions of this region Mr. Horsley had found that there was a consequent change in the emotional character of the patient. He protested against cases of injury to the frontal lobes in children being brought forward in support of the opposite view, holding, as he did, that the emotions of a child were very immature until the various functions, especially the sexual feelings, had been developed. The same argument applied to experiments on the lower animals.—Sir ANDREW CLARK said that there were two works of ancient order which might well be consulted on the question of injury and disease of the brain. Dr. Abercrombie of Edinburgh and Baron Larry had left behind them valuable records.—Dr. HUGHES BENNETT considered that when tumours grew in a very slow manner there might be no symptoms. But when the history of the case showed that there were no symptoms, was that sufficient evidence that no symptons really existed? When the motor regions were involved the symptoms were objective and apparent; now, symptoms might exist when other regions were affected, and yet special care would be required to elicit mental alterations. The "American crow-bar" was referred to as showing that some mental changes do occur after injury to the frontal lobe.—Mr. VICTOR HORSLEY remarked that in this celebrated case the man lost his affection for his fellow creatures, a fact which also supported the theory he had advanced.—Dr. FREDERICK TAYLOR referred to some cases which would bear out Mr. Horsley's suggestions. In one instance the patient had a tumour the size of a hen's egg, situate in the frontal region. The tumour was operated on by Mr. Birkett, but as it seemed to grow deeply the operation was not completed. This patient was troublesome, talkative, and made improper and indecent remarks to the students towards the end of her life. Post-mortem examination showed an abscess in each frontal lobe. Another case was referred to of a similar kind, and there was a surgical affection of the frontal lobes. A case was now under observation in which the frontal lobe of the brain was probably involved in a girl aged ten years; there was a curious mental condition, the child was more childish than usual, but it was difficult to say whether this was really abnormal.—Dr. SEYMOUR TAYLOR spoke of the possibility of two mental acts being performed at the same time. It was a matter of education, as could not be doubted when watching the movements of skilled artisans and telegraph clerks who performed two intellectual actions at once. It was common for some musicians to read and play music of which the bass clef was written in one time and the treble clef in another. Chopin was remarkable for these modes of thought. Again, weavers make many complicated movements at one time, and may even perform triangular and circular movements at the same moment. Infants at birth were pictures of a lively emotional display, and so he could not agree that the emotions were a late acquirement.—Dr. HALE WHITE, in reply, thanked Dr. Moxon for his suggestion as to the cause of the sudden death, but even then it was difficult to say what was the determining cause of the death at a particular moment. In his first case it was clear that the higher affections were not lost in any degree. He still held that the expression of the emotions were lately acquired, for it required actors and orators to give character to special emotional features by means of the expression put on the face. Tumours growing slowly in other parts of the brain do produce symptoms, and so he did not concur with Dr. Hughes Bennett's remarks.

Dr. J. J. PRINGLE described a case of Recurrent Hæmatemesis with Urticaria in a gentleman, aged fifty-one, with no family history of gout, hæmophilia, or other disorder. In 1872 he had two attacks of ordinary nettlerash, attributed to indiscretions of diet. In 1878 he had several attacks of severe nettlerash with great prostration. In 1879 these recurred with increasing frequency and severity, the tongue, mouth, and fauces being involved, and clear, watery fluid being vomited. In the latter part of the year small quantities of altered blood were also ejected. During 1880 the patient was never free from urticaria or its subjective symptoms, and at intervals of about two months attacks of great severity occurred, during which vomiting often lasted twenty-four hours at a time, large quantities of pure red blood being ejected. These attacks diminished in frequency, but continued to increase in intensity in 1881 and 1882, culminating in November of the latter year in an attack in which the blood vomited filled two hand-basins besides saturating the bed. The next attack occurred in April, 1883, and its latter part was witnessed by the writer, kindly accompanied by Dr. Wilks and by Dr. Hurd-Wood, of Leatherhead, who had watched the case from its commencement. Bright-pink urticarial wheals, nowhere purpuric, were thickly studded over the trunk and extremities; the blood vomited filled a large hand-basin; the patient's general condition was such as may be inferred from the loss of blood and the free use of morphia subcutaneously, which had been found the only means of use in allaying sickness. Recovery ensued as usual, the patient always recuperating with amazing rapidity. Shortly afterwards he had two unequivocal attacks of gout affecting the right foot and left hand respectively; the subsequent attacks have been less frequent and less severe, and apparently controlled by subcutaneous injections of morphia and ergotin, used as soon as the nettlerash appeared and nausea was felt. Three days after one of these arrested attacks a copious tarry motion was passed, and in another attack, in which a little altered blood had been vomited before the injections were used, all gastric symptoms were immediately allayed, although copious crops of nettlerash made their appearance for three days. Previous to some of the attacks there have been evidences of hepatic derangement. The immediate exciting cause in almost every instance had been exposure to cold, to which the patient was formerly very susceptible. In the intervals he is free from pain and all other symptoms of gastric disorder or ulcer. The liver and spleen are of normal size both during and between the attacks. The urine passed during the attacks had never contained blood; in the intervals its specific gravity ranges from 1020-1025; it is often loaded with urates, and invariably contains a large excess of uric acid; it is free from albumen, sugar, and casts. The radial pulse is hard, tracings from it being flat-topped. There is no decided cardiac hypertrophy; the second sound over the aortic area is accentuated; the fundus in both eyes is normal. Minute doubtful tophi have appeared in the right ear within the last six months. From the absence of all symptoms of gastric ulcer, except the vomiting of blood or other causes of hæmatemesis, and from a general consideration of all the features of the case, the writer expressed himself as forced to the conclusion that the hæmatemesis was due to capillary rupture, occurring when the gastric mucous membrane was in an urticarial condition. Presuming the possibility of such a condition, he considered that the great vascularity of the organ and the position of its rich capillary network, separated from its cavity only by a delicate membrane and a single layer of cells, account for the occurrence of hæmorrhage and for its amount. No exactly similar cases have been described; but Murchison mentions the case of a boy of nine years of age with urticaria tuberosa and purpura urticans, and with hæmorrhage from the bowels, kidneys, and urinary passages, and with the discharge of much lithic acid in the urine. Cases described by Graves as "exanthema hæmorrhagicum" present also certain points of similarity. The relationship between hepatic disorder, the gouty condition, and skin eruptions in general was merely referred to.—Sir ANDREW CLARK was much interested in the paper. Some years ago he publicly refused to accept the spasmodic theory of asthma, believing the affection to be a sort of urticaria of the bronchial mucous membrane. Many asthmatical patients were subject to urticaria, and other mem-

bers of the family suffered from urticaria. In the nasal mucous membrane, in cases of hay asthma, appearances very much like those that Dr. Pringle described could be seen. Dermatological treatises were singularly deficient in their account of eruptions affecting mucous membranes. The occurrence of eczema on mucous membranes of the stomach and elsewhere is frequent, and is overlooked in works on dermatology.—Dr. STEPHEN MACKENZIE believed that the views advanced by Dr. Pringle were sound. The association of urticaria with hæmatemesis had some resemblance to the association of urticaria with paroxysmal hæmoglobinuria. Urticaria, and the passage of blood-colouring matter in the urine, followed on exposure to cold, and might occur in one and the same patient, as he had shown. Dr. Pavy believed that a vaso-motor condition was at the foundation of paroxysmal hæmoglobinuria, just as urticaria had a similar basis. The pathology of urticaria really explained the whole case. There was first spasmodic contraction of the vessels, followed by paralytic dilatation with exudation of fluid, and even occasionally of blood-corpuscles, as was seen in cases of purpuric urticaria. Imagine the same set of changes occurring in the glomeruli of the kidney, where the blood was injuriously compressed and the hæmoglobin expressed from the corpuscles, and the pathology of paroxysmal hæmoglobinuria is laid bare. A case was quoted to show that herpes may occur on the mucous membranes of the mouth and œsophagus in conjunction with herpes of the skin about the mouth. The influence of the nervous system in determining such lesions appeared to him to be by no means far-fetched.—Dr. WILBERFORCE SMITH inquired into the duration of the illness from which the patient suffered whilst in India.—Dr. PRINGLE, in reply, said that the man suffered only fourteen days out of seven years, and the dysentery and ague with which he was affected were both included in that period. Geneau de Mussy had spoken of "endanthemes" as opposed to exanthems; and Leube, writing in Kaposi's "Hautkrankheiten," held views similar to those of Dr. Stephen Mackenzie on herpes.

The following living specimens were shown:—Mr. Bernard Roth: a case of Hydrocephalus in a boy aged sixteen, who could not stand alone. Mr. Rickman J. Godlee: a case of Severe Wound of the Wrist, ending in recovery with movable joint.

MEDICAL SOCIETY OF LONDON.

Comma Bacilli of Koch, Finkler, and Prior.—Aphasia without Lesion of Broca's Convolution.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, F.R.C.S., President, in the chair. The proceedings were more than ordinarily interesting.

Dr. G. HERON showed specimens of the Comma Bacillus, described by Koch as occurring in cholera, and of the comma bacillus found by Finkler and Prior in the stools of cholera nostras, thirteen or fourteen days old. He said that he had no intention of discussing the causal connexion between the comma bacillus of Koch and cholera, but proposed to deal only with certain peculiarities of the two varieties of bacilli referred to. The comma bacillus of Finkler and Prior was associated with decomposition, and its cultivations evolved a slight putrefactive odour; it closely resembled Koch's comma bacillus when seen under the microscope, but much importance could not be attached to such a resemblance. When planted on nutritive beef jelly both organisms grew and multiplied, but in a very different way. At ordinary temperatures, 60° F., the bacillus of Finkler and Prior grew with great rapidity, producing an appearance, on or about the second or third day, which was characteristic; the gelatine in the neighbourhood of the puncture made by the inoculating wire was liquefied and permeated by a homogeneous opaque growth, having the appearance somewhat resembling the finger of a glove, or, as has been said, the toe of a stocking pushed into the gelatine. The bacillus of Koch grew very much less rapidly under the same conditions. On the third and fourth days the track of the inoculating wire was marked only by a thin line of scattered points at which the comma bacillus was slowly growing. The differences in the mode of growth were constant, and afforded a means of distinguishing between the two organisms. When sown on potatoes the bacillus of Finkler and Prior grew with great rapidity, but the bacillus of Koch developed only very slightly. The specimens shown illustrated these points of difference in a very striking manner. These peculiarities of growth were not in accord with the statement made by the English Cholera Commission.—Dr. COUPLAND thought we could now thoroughly understand Koch's position. Dr. Heron had not mentioned that Finkler and Prior believed that their bacillus was the cause of simple cholera or cholera nostras, and hence we might infer that Asiatic cholera and cholera nostras were probably of the same nature. He considered it certain that these organisms were of very different nature. He paid a tribute to Koch's scientific accuracy and caution.—Dr. HERON briefly replied, concurring in the remarks of Dr. Coupland that Koch was a man who used the utmost care in carrying out his experiments.

Dr. SAMUEL WEST read a paper on a case of Aphasia in which the chief lesion was situate in the supramarginal and angular gyri, Broca's convolution being healthy. A man aged sixty-six came under treatment for bronchitis, with weak heart and granular kidneys. While in the hospital he became suddenly aphasic, but did not lose consciousness, nor was his general condition otherwise affected. In addition to the aphasia the patient had some loss of power in the right side of the face, in the right arm and leg, and also incomplete hæmianæsthesia. The patient retained certain words in common use, such as "good morning," "yes," "order," "corner," "one or two with it," which he was in the habit of using in his occupation of carrier. When he attempted to say more than this he broke into an unintelligible gibberish; occasionally he would say "I can't," "I couldn't," as if to express his sense of inability to express himself. He could not name visible objects, though he understood their use, and would take them in his hand and perform certain movements upon paper as if wishing to write, though nothing intelligible was produced. He could not read printing nor manuscript, though he held the paper the right way up. He misunderstood most that was said to him, and would perform certain acts when told to do so; it was evident that he understood simple questions; occasionally he could speak words spoken to him (parrot speech). His powers in all the above respects varied greatly at different times. Death ensued from exhaustion six weeks after the onset of the aphasia. At the autopsy granular kidneys were found; the heart was dilated and fatty, and there were signs of bronchitis. In the brain a large area of softening was found in the region of the supramarginal and angular gyri; Broca's convolution was intact. The softening extended through the whole depth of the convolution into the centre of the supramarginal gyrus, but elsewhere was not so deep. On section the alteration was found to have extended into the root of the ascending parietal convolution, and to have involved also the deeper portions of the ascending parietal convolution in direct continuity with the supramarginal convolution, as well as the superior temporo-sphenoidal convolution in immediate proximity to the fissure of Sylvius. The island of Reil was affected throughout its whole extent, but the external and internal capsule had completely escaped. The cause of the softening was clearly plugging of the branch of the Sylvian artery, which is distributed to the parts affected. The clinical symptoms were those of the amnesic and not of the ataxic form of aphasia, and are in perfect accord with the pathological lesion. The visual centre was most affected, and this is placed in the supramarginal and angular gyri where the lesion was most extensive. The auditory centre was affected but to a much less degree, and the arm, leg, and face centres were also damaged. The hemianæsthesia seemed not to be accounted for. The lesion of the island of Reil could not be associated with any definite symptoms. The entire case was in complete accord with the present doctrine of cerebral localisation.—Dr. BROADBENT said that the case had been most carefully and completely described. The only criticism he should offer on the case was as to its name. Aphasia should be restricted to the motor affections of speech, and amnesia to the disturbances on the sensory side of language. He had seen several cases, and some in which the loss of apprehension was more complete than in Dr. West's case. The motor conjunctions were completely spared; there was transient hemiplegia, but persistent right hemianæsthesia. The patient spoke the most complete gibberish, but with such appropriate gesture that it was evident he understood. Sometimes, under great excitement, a whole phrase would slip out. Besides such complete loss of apprehension he had seen a great many cases of minor affection. A case was

narrated in which a man talked intelligently, and held a conversation without the slightest slip, but he could not name a single object at sight; he was unable to read; he could recognise his own signature at sight; he could write letters perfectly well. In this case there was a hæmorrhage lying immediately beneath the angular gyrus. The term "word blindness" is inadequate, for in every such case there was loss of power of naming at sight. In these instances there was a breach of communication between the visual perceptive centres and those centres where the auditory perception corresponding to it was located - viz., its name. Intelligent reading was impossible without the faculty of naming objects at sight. Another case was mentioned in which it was supposed that a lesion existed about the angular gyrus of the right side; disturbances occasionally took place around this focus, at one time causing aphasia with right hemiplegia and lateral deviation of the eyes to the left. He had seen cases of word deafness in which the patients did not understand what was said to them; these patients sometimes answered in gibberish, at others, reply to a question would be utterly inappropriate. Other cases of aphasia and amnesia were also detailed.—Dr. S. WEST briefly replied.

OPHTHALMOLOGICAL SOCIETY.

New Ophthalmoscopes.—Influence of Vapours of Bisulphide of Carbon and of Chloride of Sulphur on the Vision and General Health.—Cocainised Eye.

AN ordinary meeting of this Society was held on Jan. 8th, Mr. Shadford Walker of Liverpool, Vice-President, in the chair.

The Hon. Sec., Dr. BRAILEY, read a communication from the Local Government Board relating to the Code of Suggestions drawn up by the Special Committee of the Ophthalmological Society, with a view to the prevention of blindness from ophthalmia neonatorum, and which code has been sent to the Local Government Board for its approval and adoption. The letter said that the code of rules had been forwarded to the Registrar-General, who replied by saying that it was not to be expected that the registrars of births would perform any extra duty without adequate compensation. If this compensation were fixed at *2d.* for each card read and presented, the cost would amount to £7300 per annum. In many cases it was not the mother who registered the birth, and if instructions were given for purulent ophthalmia, why not for all the other diseases to which infants are liable? The whole scheme was impracticable. As to the relieving officers, the Local Government Board said that their labours were already sufficiently arduous.—On the motion of Dr. STEPHEN MACKENZIE, seconded by Mr. SYMPSON, it was resolved that the deputation which waited on the Local Government Board should be appointed as a Special Committee to consider what should be done in respect of the above communication.

Mr. F. R. CROSS of Bristol showed a specimen of Cystic Tumour of Iris in a woman aged thirty. It was the size of a pea, and protruded into the anterior chamber, pushing up the iris, to which it was attached. She had first noticed something wrong with her eye two years and nine months earlier, when she believed a foreign body had been blown into her eye; this was followed by some irritation of the eye, and a small spot was noticed; this spot enlarged and attained the size of a pea, but after a year subsided to the size of a pin's head, and again enlarged to its present size.

Mr. R. MARCUS GUNN showed a new Ophthalmoscope with a thumb movement of the discs and a strong flat handle. The flat handle was utilised as a pupilometer and a measuring scale. At the end was an aperture useful in testing for central colour scotoma. The thumb movement gives increased steadiness and uniformity.

Mr. STANFORD MORTON exhibited an Improved Student's Ophthalmoscope, which had been constructed for him by Messrs. Pickard and Curry. It combines the various improvements of several ophthalmoscopes. For all ordinary purposes it has only a single series of lenses, but four extra lenses, easily adjustable, are provided for special occasions. The numbers of the lenses are fully exposed on a dial plate, so that the position of any required lens is at once manifest and the lens at the sight hole is always indicated at the same aperture. There are two mirrors (one fixed at an angle), either of which can be instantly turned into position. The instrument is an inch and a quarter wide, and there is only one driving wheel, which, being three inches below the sight hole, is not impeded in its action by the face of either patient or observer. The ophthalmoscope balances well in the hand, is light, and packs into a small compass.

Mr. J. COUPER showed a new Refraction Ophthalmoscope. Last year a refraction ophthalmoscope on a new principle was submitted to the Society. Discs, combinations of lenses, and multiple refraction were dispensed with in it. Single lenses, of which there were seventy-two, were alone used. One mirror with diametral hinge was made to serve for both direct and indirect examination, as well as for retinoscopy. The object was to simplify the mechanism and increase the optical efficiency of the ophthalmoscope. The chief faults of the instrument in its original form were:—(1) Its bulk; (2) the slow propulsion of the lenses; (3) the effort required to turn the driving wheel; (4) uncertainty in reading the index wheel, from the circumstance that the shutter as well as the mirror must be shifted from side to side by hand, in order to make the figure and the lens at the sight hole correspond. If the mirror were shifted without the shutter the index read false. New instruments were placed in comparison with the old to show how far these defects have been lessened. In the most recent the index wheel becomes the driving wheel (coarse adjustment). One revolution of it brings each of the seventy-two lenses in turn to the sight hole, and a half turn suffices to go from the lowest to the highest lens of either series. Even with this wheel the lenses are readily centred at the sight hole. A fine adjustment wheel has been added, however, to give a slower, lighter movement, which is found convenient towards the close of an examination. Only one figure at a time appears at the aperture of the shutter, and the latter follows the movements of the mirror automatically; a false reading thus becomes impossible. For those who are satisfied with fewer than seventy-two lenses, a thirty-six lens instrument has been provided.

Mr. WM. LANG showed a Modification of Purvis's Original Instrument, made by Messrs. Ferrier and Watson. Two discs carrying the lenses were moved by milled wheels which were conveniently placed; by a simple combination it can produce from −1 to −29 and from +1 to +29. He also showed a Pupilometer consisting of a plate fixed at the back of an ordinary retinoscopy mirror.—Mr. COUPER doubted the desirability of having two mirrors attached to an ophthalmoscope, and preferred a very small sight hole and a mirror of long focal distance.—Mr. STANFORD MORTON thought the best illumination was obtained with a mirror of nine or ten inches focal length.—Mr. JOHNSON preferred a mirror of focal length of four or five inches for direct examination, and a special mirror with a focal length of about nine inches for keratoscopy.

Dr. W. A. BRAILEY showed Microscopic Specimens of the Condition of the Ciliary Nerve in a case of Sympathetic Disease. The left (sympathising) eye was excised on account of loss of sight, severe inflammation, and pain. The right (exciting) eye was operated on for cataract eleven months ago. Four months later opaque membrane was needled; five months later the left eye was found to be quite blind from iritis, presumably sympathetic. The long ciliary nerve and artery are perfectly normal. A section was shown of a perfectly normal long ciliary nerve and artery of an eye which had been excised on account of exciting sympathetic uveitis; the eye was injured thirteen weeks ago; the adjacent choroid was in a state of severe inflammation.

Dr. W. A. BRAILEY also exhibited Microscopic Specimens of an Exceptional Condition of the Ciliary Nerves in three cases of Uveitis. One section showed inflammation round the internal long ciliary artery extending into the contiguous portion of the corresponding long ciliary nerves. The eye was excised on account of iritis, with recurring tension, one month after the extraction of the cataract from a glaucomatous eye. The second section was very similar; it was taken from a case of iritis following an iridectomy; the other eye was sympathetically irritated. The third section showed severe neuritis of the long internal ciliary in an eye due to severe irido-choroiditis of spontaneous origin.

Mr. NETTLESHIP exhibited a patient with Universal Detachment of the Retina from the edge of the Optic Disc forwards in all directions as far as could be seen; the greater part of the retina remained transparent; at the fovea centralis the retina was hypermetropic seven or eight dioptrics, the physiological cup of the optic disc was slightly

myopic. The patient had good perception of light, and with + 8 D. or + 18 D. he could count fingers and see letters in 20 Jaeger. The vision and refraction of the right eye were normal. The patient was a teacher, aged seventeen; divergent squint of the left eye had been noticed for about eight years, and about that time he had a blow on the head; there was no evidence beyond this to show when the detachment occurred.

Mr. HARTRIDGE showed a case and a water-colour drawing by Mr. Morton of Opaque Nerve Fibres completely encircling the disc and extending for a long way over the fundus of the right eye. There was considerable myopia.

Mr. JESSOP showed specimens of Tubercle Bacilli growing in blood-serum and in the iris of the rabbit.

Mr. F. R. CROSS of Bristol exhibited a case of Symmetrical Dislocation of Lenses upwards of congenital origin. The patient was eight years of age. Each eye was practically similar. The iris was tremulous, and the lower edge of the lens appeared just below the upper edge of the pupil. The ophthalmoscope showed a double image of the optic disc. Under the use of atropine the edge of the lens was distinctly seen to cross the pupil.

Dr. W. A. BRAILEY showed a living specimen of Hyphæma. A month ago she had in the left eye hyphæma with varying tension and slight iritis, all these symptoms being of about three months' standing only. Before that there were large floating opacities, probably blood, in the vitreous, with great pain round the eye and in the forehead. The right eye had its pupil occluded and excluded, with shallow anterior chamber. Both supra-trochlear nerves had been recently stretched, with some relief to the pain. On Dec. 15th the iritis in the left eye became worse and the anterior chamber deeper, till now it is of enormous depth, but symmetrically so. The aqueous humour is clear. There is a greyish hazy reflex from behind the pupil. On Dec. 18th the right eye had a slight attack of a similar nature—i.e., its anterior chamber became deeper with ciliary injection. Thus was revealed the existence of six marginal anterior synechiæ. In a week the right eye regained its former condition, but the left eye still has enormously deep anterior chamber, with the other symptoms mentioned. The disease began in the right eye two years and a half ago, and in the left eye eighteen months ago. In this eye there were then films in the vitreous with failing sight and severe pains round the eye, but no other direct evidence of inflammation. The right eye was as at present. The author asked—1. What is the nature of the uveitis? 2. What is the cause of the increased depth of the anterior chamber and the varying tension?

Another patient was shown, who had had a blow on the left eye with a nail five months ago; since then there had developed diminished tension with defective vision. Now there was a small superficial corneal opacity with shallow anterior chamber, and a patch of slight opacity on the posterior surface of the lens.

Mr. ADAMS FROST read the report of the Committee on Poisoning by Bisulphide of Carbon and Chloride of Sulphur, signed by himself, Mr. Gunn, and Mr. Nettleship. The affection, they said, had long been recognised in France, and had been well described by Dr. A. Delpech, who grouped the symptoms into two stages—namely, a stage of excitement and a stage of depression. The affection had also been described in this country by Dr. Alexander Bruce. It appeared that there were only a very few firms engaged in the manufacture of indiarubber by Parkes' process, which was admittedly the one most liable to be followed by symptoms of ill-health. The reporters referred in some detail to the various steps of the process, which appeared to involve the greatest amount of risk, and pointed out the methods by which they believed that in some degree these dangers might be obviated. Out of the thirty-three recorded cases, in twenty-four there was some affection of vision. The prognosis appeared to be tolerably favourable, if the patient were able to give up his work at an early period after the first appearance of the symptoms. They were unable to draw any definite conclusions as to the length of time of exposure to the noxious influence necessary for the production of the symptoms; slight symptoms, however, were often noticed a few days after commencing the work. The amblyopia was never an isolated symptom, and never occurred without well-marked general toxic symptoms. In most of the cases which were seen by oculists, decided changes were seen at the optic discs; in the earlier stages, haziness and other signs of caronic neuritis, in the later stages some degree of atrophy or pallor. In some, central defect of the field was found, but this had not been carefully examined, except in a very few instances. Several patients were noted as smokers, and a good many were stated to have been particularly temperate.

Mr. WALTER H. JESSOP read a paper on the Cocainised Eye. An eye under the influence of a local application of cocaine presents the following symptoms:—Anæsthesia of the parts in intimate contact with the drug; enlargement of the palpebral fissure, mydriasis, loss of accommodation, constriction of the small peripheral vessels, flaccidity of the cornea, and slightly altered intraocular tension. The enlargement of the palpebral fissure is due to the retraction of both upper and lower lids by irritation of the unstriped muscular fibres contained in them, probably through their nerve supply from the sympathetic. The dilatation of the pupil always acts to light and to the movements of accommodation, and this, coupled with the actions of atropine, pilocarpine, and eserine on the mydriasis proves its sympathetic origin. The paralysis of accommodation occurs chiefly at the period of greatest dilatation of the pupil, and disappears some time before the pupil regains its normal size. The small peripheral vessels are constricted, producing pallor of the conjunctiva, but this rarely occurs except in normal vessels, and does not last long, showing irritation of the vaso-constrictor filaments of the sympathetic. The flaccidity of the cornea apparently is accompanied by diminished tension in the anterior chamber, but at the same time a brief increase of tension may be noticed posteriorly. The circulation and sensibility of the retina are not affected by conjunctival instillation. From the above facts, and from the action of cocaine on other organs, it is probable that it acts locally, paralysing the peripheral endings of the sensory nerves and irritating the sympathetic. The uses to which the drug may be put in ophthalmic practice are:—(1) As a local anæsthetic in operation cases, ulcers of the cornea, &c.; (2) as a mydriatic for ophthalmoscopic purposes, and combined with atropine in iritis with synechiæ; (3) as a means of paralysing the accommodation in cases in which atropine or homatropine cannot be used. The salt used in all the experiments was the hydrochlorate in 2·4 or 20 per cent. solution, and it had been applied by conjunctival instillation and injection beneath the skin, fascia, or into the anterior chamber. It may be mentioned that in one case of iritis which had been treated by the frequent instillation of atropine into the eye for a fortnight the cocaine still exercised its mydriatic action.

ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Pathological Section was held on Dec. 5th, the President, Dr. Foot, in the chair.

Surgeon-Major HAMILTON made the following communication. A soldier of fine physique, aged thirty, was admitted to the Portobello Hospital complaining of palpitation. He had been for some time employed on police work, and he knew that his heart was affected. There were extreme præcordial dulness, a well-marked systolic bruit at apex and over base, and a loud systolic and regurgitant bruit. His condition remained the same for about a month, when anasarca set in, rapidly increasing. He sat up one night against orders and died almost immediately. Post-mortem examination:—The viscera, with the exception of the heart, were all healthy, but the serous cavities and cellular tissue contained much fluid. The heart, enormously enlarged, weighed one pound twelve ounces. Mr. Abraham examined it, and found all the cavities dilated and the walls hypertrophied. The inner surface of the pulmonary artery was of a remarkably deep-purple colour. The principal lesion was seen in the aorta and its valve. Large bulging particles of atheroma, not calcified, existed in the ascending arch, and between the openings of the coronary arteries a large, rough calcareous nodule projected opposite the junction of the anterior and left posterior segments of the valve, which were here confluent; and at this point of the valve was a wide irregular opening, admitting a large finger. The rest of the valve was more or less thickened and frayed, and an ulcerated spot was to be seen on the ventricular surface. Just below the nodule a cavity two centimetres wide and one centimetre deep extended below the bottom of the sinus behind the endocardium and into the muscular substance of the heart. Mr. Abraham called attention to the microscopic preparations of the specimens which were exhibited.

Mr. ARTHUR BAKER read the notes of a case in which he

had removed from the left side of the upper jaw of a lady a small osteoma. The fact that such growths rarely occur in situations where diagnosis is attended with difficulty made the case interesting, since it was impossible before removal to tell that the growth in question was not a buried tooth or an odontome, springing as it did from the site of the first left upper molar tooth. The case was further complicated by the existence of a cyst near the front of the jaw, combined with absence of the permanent canine tooth. The tumour on section showed lacunæ disposed irregularly round the vascular canals, which penetrated its substance for some distance. Near the periphery, however, some lacunæ were seen arranged in parallel rows. The communication was illustrated by a cast of the mouth and some etchings of the microscopic and macroscopic appearances of this growth.

Dr. QUINLAN submitted a case of Cancerous Stricture in the Sigmoid Flexure of the Rectum. A woman, aged forty-seven, in a state of great prostation and partial collapse, was admitted into St. Vincent's Hospital. Her abdomen was enormously distended, her bowels not having been relieved for eleven days. A turpentine enema was administered, but came away without effect. On examining the rectum, he thought he perceived a tumour, but it was beyond the reach of his fingers. Great distension of the abdomen prevented an exact diagnosis, and treatment was altogether directed to getting the bowels to act and to keep down pain. Some vomiting was quickly relieved. On the third day she sat up, vomited, and fell back dead. At the post-mortem the body was found emaciated and bloodless. The small intestines were enormously distended with gas. The descending colon was full of fæces. At the sigmoid flexure the cause of the obstruction was found to be a cancerous mass of a malignant character. Beneath the rectum was a peculiar structure affected by malignant disease. Mr. Abraham had pronounced the tumour to be an infiltrating adenoma, caseating in parts.

Mr. O'GRADY exhibited a case of Strangulation within a Hernial Sac, the specimen being from the body of a man aged thirty-three. The hernia came down in the ring. He was admitted into the hospital at 1 o'clock. The symptoms being urgent, he was operated on at 5 o'clock. When the sac was exposed a tense stricture appeared at the external rim. The intestine, a little highly coloured, could be seen through the sac. The hernia was reduced without opening the sac. For two days after the operation, with the exception of two attacks of vomiting, which were relieved, he was free from the usual symptoms. On the third day the stomach sickness with pain returned, and he died the next day, eighty-seven hours after the operation. The question as to when internal strangulation occurred was of interest. It was not tight, and the gaseous contents of the intestine could be passed backwards and forwards. Another question was the expediency of the operation without opening the sac. This case did not exhibit such symptoms as to indicate that course, yet events showed that had the sac been opened he might have recovered.

Mr. NIXON exhibited a Hard Calculus removed from one of the tonsils of a gentleman who complained of a slight obstruction of his throat. Being in the habit of singing, he complained of the obstruction. Both tonsils were considerably enlarged. Detecting a small white speck, the probe elicited a metallic ring. Having failed to grasp the mass with instruments, he enucleated it with his finger. The greater portion was up behind the soft palate. There was considerable hæmorrhage.—Professor BENNETT said the specimen was of great rarity, and moved that it be submitted to the Committee of Reference to ascertain its constitution. It indicated articulation either with another calculus or adjoining bone.—Mr. CORBETT thought the formation was identical with the tartar that often formed about neglected teeth, resulting from constitutional disposition. He had seen several teeth blocked together by it even in young mouths.—Mr. NIXON, in reply, said the gentleman's tonsils were very large, and were not atrophied. The calculus was similar to the tartar formation on teeth. The facet was observable. The teeth were black and hard, and had a good deal of tartar. The gentleman was a great smoker.

The Secretary, Mr. ABRAHAM, for Mr. J. K. BARTON, exhibited a large Mammary Tumour removed at the Adelaide Hospital from a girl aged twelve. Her grandmother had died of recurring cancer of the breast. One brother was now suffering from Pott's caries. The other near relatives were well. The girl's general health had been good and there was no history of injury to the breast. Three months ago a small lump was observed in the left breast, which increased steadily, being at first painful. Mr. Abraham reported the consistence of the tumour to be soft, homogeneous, and elastic; the cut surface bulging and the whole easily peeling out from the surrounding encapsulating tissue. The microscopic sections exhibited enlarged glandular alveoli lined with proliferating epithelium, and separated by thick septa, principally made up of embryonic and spindle-shaped cells, resembling some form of sarcoma. He regarded the growth as a form of adenoma, with cellular hyperplasia of the interalveolar tissue, and he suggested its reference for further consideration to the Committee of Reference. The specimen was, on the motion of Mr. Abraham, seconded by Professor Bennett, referred to the committee, Professor Bennett observing that last year he himself showed a tumour of a character usually regarded as benign fibroma of the breast, weighing about fourteen pounds, but though its removal was effected in a complete manner, tumours recurred in six months in the axilla, neck, and in every direction, some being as big as a man's head.

Analytical Records.

[WE think it right to direct attention to the system we adopt in the conduct of this department. Of the numerous articles of food and medicine submitted to us we select such as we think important to the medical profession and the public. Samples of these are bought by us in the ordinary way, and the results of our examinations reported.)

EXT. CINCHONÆ LIQ., DE VRIJ.

(DE VRIJ'S EXT. CINCHONÆ LIQ. COMPANY, FISHER-STREET, RED LION-SQUARE.)

This is a concentrated extract of red bark, prepared, we are told, in vacuo to avoid the oxidation of the natural acid. Dr. De Vrij, whose authority none will dispute, superintends the manufacture, and great care is taken to use bark, or mixtures of bark, of uniform composition. The manufacturers guarantee the presence of 7 per cent. of the cinchotannates of the alkaloids. These are great advantages. Unscrupulous makers are apt to be careless in the selection of the bark, and physicians are therefore apt to distrust cinchona extracts. Of course, we can only speak of the sample we have examined, but that we find to be exceedingly satisfactory. The rough test of liquor potassæ shows the large quantity of alkaloid contained in the extract, and more careful analysis proves that a due proportion of quinine, as well as the other alkaloids, is present.

ERGOTININE DE TANRET.

(WILCOX & CO., OXFORD-STREET.)

It is, of course, impossible by chemical analysis to ascertain the physiological activity on which the true value of this preparation depends. The ordinary tests show, however, that it is a genuine preparation of ergot, and as such we commend it to the notice of the medical profession. The solution is especially intended for hypodermic injection, and is said to have been adopted in the Maternité de Paris.

SANITARY FLAKE CHARCOAL.

(CAMPBELL & CO., PAISLEY.)

The practical use of wood-charcoal as a disinfectant dates from the well-known experiments of Dr. Stenhouse. Its oxidising power is remarkable, and it might be much more generally used than it is at present. It should be applied in small fragments, as free as possible from dust; and in such a form Messrs. Campbell supply it at an extremely low price. The sample sent to us had a specific gravity of 0·301 and yielded 1·26 per cent. of ash. It was therefore an excellent charcoal, well adapted for sanitary purposes, for which we heartily recommend it.

THE LANCET.

LONDON: SATURDAY, JANUARY 17, 1885.

LAST week we were able to announce two events which may be of good omen. On the 2nd instant the President of the Royal College of Surgeons of England received a deputation of the Association of Members of the College in reference to certain corporate rights and privileges claimed by the Members; and on the 8th instant the Council itself requested the President to invite the Association of Fellows to send delegates to the Committee on Charters and Bye-laws in order that the committee may confer with them respecting some alterations proposed to be made in the Charters and Bye-laws. Were we to adhere too rigidly to the teachings of past experience, we should not be sanguine of a satisfactory result of these conferences and deputations; but we would fain hope that the Council is at length beginning to be sensible of the reality of the organised opposition it must encounter if it continues to pursue its old policy of isolation and distrust. Ever since the establishment of the College, eighty-four years ago, the executive body has followed a line of conduct which has begotten the disaffection and the antagonism of the Members. Fifty-nine years ago more than a thousand Members of the College met together to protest against the abuses of the Council, and to agitate for some reform in its constitution. At that meeting it was resolved that the Members of the Council should be elected annually by the Members (there were no Fellows at that time), and that *each Member* should have a voice in the election. In March last, or fifty-eight years later, a general meeting of Fellows and Members was held in the College, when recommendations were adopted to the effect that the Fellows and Members should have a larger share in the management of the College, and that no alteration should be made in its constitution without the consent of the Fellows and Members, convened to discuss such alteration. The Council has *twice* deliberately refused to give effect to these recommendations. But the Association of Fellows has again submitted these recommendations to the Council, and has requested an appeal to the Fellows and Members. The meaning of this is too plain to be missed; and with the Association of Members threatening an approach, the Council is induced to ask a truce, and to seek a conference. At this stage outsiders may be content to suspend their judgment and await the issue. One thing is certain: the loyalty of the Fellows and Members to the College will finally overcome all the obstruction and prejudice which the present tenants of seats at the Council board inherit from a long line of predecessors. The Council alone is not the College, but the Council *and* the Fellows and Members.

ALTHOUGH the pathology of the affection known as paroxysmal hæmoglobinuria is still shrouded in obscurity, there have not been wanting numerous researches, mostly on the experimental side, which may eventually be found to throw light upon the condition. We say eventually, because each series of observations stands, as it were, apart, and there remains a wide gap still to be filled between the condition observed as a spontaneous affection in man and that artificially excited in animals. The questions which are most open for inquiry group themselves around its etiology. Is it a blood disease? or is it primarily a renal derangement? If malarial influences have no share in its production, what other agencies can explain its intermittent character? If exposure to cold is to be recognised as an exciting cause, how does it operate? These and other points too numerous to mention invest the affection with an interest which would be more widespread if the condition were more common. As it is, they suffice to render it imperative that every case as it occurs should be thoroughly sifted, for a satisfactory explanation of its phenomena may throw light upon the physiology of the kidney, as well as on its derangements. The most recent attempt to elucidate the subject is to be found in the current number of VIRCHOW'S *Archiv*, in an article by Dr. AFANASSIEW of St. Petersburg, based on an experimental research carried on by him in COHNHEIM'S laboratory at Leipsic. The aim of this inquiry was to observe the effects produced by the destruction of red blood-corpuscles within the living body, and the consequent setting free of hæmoglobin, either in the form of organic particles or in a state of solution in the serum of the blood. In that way a condition of hæmoglobinuria was set up, and by varying the agencies employed different degrees of the condition were established, and a more or less exact imitation of the human paroxysmal affection was obtained. The substances employed were glycerine, pyrogallic acid, and toluylendiamin, which, when administered (mostly subcutaneously) to dogs and rabbits, produced more or less marked hæmoglobinuria. Glycerine possesses the property of extracting hæmoglobin from the coloured corpuscles and causing its solution in the plasma. If the dose be a small one, hæmoglobinæmia is the sole effect; but a larger amount is soon followed by definite hæmoglobinuria. Jaundice, however, is not produced. Toluylendiamin breaks up the red corpuscles, so that the blood becomes filled with coloured granules, which accumulate in the liver, spleen, bone-marrow, and also in the kidneys; but, unlike the glycerine cases, there is no hæmoglobin held in solution. With feeble doses, jaundice, described as hæmohepatogenous, is present, with albuminuria; with stronger doses there are both jaundice and hæmoglobinuria, and the animals rapidly succumb. Pyrogallic acid has an action intermediate to the other two agents, extracting hæmoglobin from the corpuscles, and producing hæmoglobinuria with very feeble icterus. Thus by the use of these various agents effects of varying intensity were produced, comparable to the different degrees of paroxysmal hæmoglobinuria observable in man; for it is known that in this affection there may or may not be evidence of blood destruction, and there may or may not be concomitant jaundice.

If, now, we turn to the effects produced on the organs most concerned, we see that in each case there is produced a marked degree of nephritis. The inflammation is most evident around the glomeruli; and the denudation of the epithelium of Bowman's capsule is associated with an escape of albumen or of hæmoglobin within the latter. There is

also, especially in the cases of glycerine poisoning, fatty degeneration or coagulation, necrosis of the renal epithelium, often combined with a deposition of lime-salts into the degenerate cells. In one case of a dog, where ten successive attacks of hæmoglobinuria had been induced by this agent, the nephritis was of an extreme kind, with hæmorrhages into the tubules. The liver in each case also undergoes fatty degeneration; and in the toluylendiamin cases, where jaundice is a particularly marked symptom, the necrotic hepatic cells are in part laden with bile-pigment and the products of blood-disintegration, there being further an infiltration of round cells around the hepatic and sublobular veins. The author next proceeds to discuss in detail the reasons for variations observed in the mode of separation of hæmoglobin from the blood and its appearance in the urine. Sometimes it appears in the form of granules, sometimes in solution, the urine in the latter case containing no casts or sediment, but yielding the characteristic spectroscopic reactions. He suggests that the colouring matter which separates from the corpuscles in the form of yellowish-brown granules is not pure hæmoglobin but a modification of it, and that the particles may either be used up in the liver or deposited in the kidneys; or else that by long persistence in the blood plasma the colouring matter is dissolved and excreted with the urine in solution. The sediment in hæmoglobinuric urine is probably not true hæmoglobin or hæmatin, for it is insoluble and does not have the spectroscopic characters. The dissolved hæmoglobin or methæmoglobin is excreted at the glomeruli, owing either to circulatory derangement or to changes in the glomerular epithelium; whereas the formed products of corpuscular destruction are never found within Bowman's capsule, but are deposited as brown granules in the tubular epithelium. In many cases bile-pigment is to be found in both these situations; and where jaundice is very marked, casts containing such pigment block the tubules. Three kinds of casts are met with in cases of "hæmohepatogenous icterus" associated with hæmoglobinuria—viz., those containing crystals of hæmatin or hæmoglobin, those containing bilirubin crystals, and those filled with the pigmented granular débris of disintegrated blood-corpuscles.

Finally, in order to obviate the errors likely to arise from the practice of employing toxic agents to destroy the blood-corpuscles, he performed some experiments of transfusion of defibrinated blood heated to about 56° C., whereby the red corpuscles are broken up and the hæmoglobin is dissolved in the serum. The effect of such a transfusion is to induce hæmoglobinuria, and the anatomical changes in the kidney and liver are precisely those which occur when the blood-corpuscles are broken up within the body by glycerine and the other agents named. This is held to be sufficient proof that these changes are not due to the direct action of these substances on the organs, but to the separation of hæmoglobin from the corpuscles, and its escape into the general blood-stream either in solution or in a granular state. Dr. AFANASSIEW feels himself justified in describing the renal lesions as hæmoglobinuric glomerulo-nephritis, which in a later stage may pass into an interstitial nephritis, and the condition of the liver he styles "hepatitis interstitialis ex ictero hæmohepatogene." As a contribution to our knowledge of an obscure subject, and particularly as a demonstration that corpuscular disintegration is capable of inducing profound structural lesions, this article may be welcomed; nevertheless it leaves untouched the etiological question, which is the most interesting and obscure of all.

THE code of rules for the prevention of infectious and contagious diseases in schools, being a series of resolutions passed by the Medical Officers of Schools Association, cannot fail to be a useful guide to practitioners engaged in attendance on either our public or private schools. We encouraged in the first instance the formation of this Association, and congratulate the members on the general usefulness of the resolutions they have passed. Some shortcomings naturally present themselves in the work of so young an Association. For example, the members appear to have lost sight of the fact that the general hygiene of all our public schools is under the direction of the sanitary authority of the district in which the school is located, and that in reality the medical attendant of the school has no *locus standi* as an officer of health. His province is essentially clinical, and the sanitary laws of the country repudiate him on matters of public hygiene. The sanitary medical officer appointed by the district authority is responsible for the sanitary arrangements of our schools, and to him should be referred questions of drainage, water-supply, &c., as the legally constituted authority. His authority does away with the possibility of "*that undivided medical responsibility*" which the members of the Association appear to us unwisely to aim at. The law refuses to recognise this "undivided responsibility," and it would be better for the medical attendant of a school to acknowledge the constituted authority of the public medical officer of health, and facilitate, after the manner of a family practitioner, the free and unimpeded working of our public sanitary laws. There is ample room for this division of labour, and the Association seems to be endeavouring to arrogate to itself an authority which it can never in reality possess.

Another clause, to the effect that "an annual return of school sickness to the *governing body* of the school from the medical officer is very desirable," falls short of what we think necessary, for it should not be confined to the governing body, but is equally due to the parents of all the pupils and to the public generally, in order that those who contemplate using the school in future may have some ground on which to judge of its sanitation. The secrecy of the past in this respect should be discouraged in the future, and the Association will deserve the gratitude of parents by doing so.

The question whether there should be a single general infirmary for infectious and non-infectious cases, or a second isolated infirmary for infectious cases, is one upon which school authorities are much divided. A boy falls ill and is feverish. He is placed in the general infirmary without suspicion of anything infectious. In a day or two he develops a rash, and the infectious nature of his malady becomes apparent. It is a drenching November day or a bitter March day, with north-east wind. What parent would approve of his child being taken through the chilling air to the separate infirmary? What medical man would sanction such a course? This, we think, pre-

sents one of the difficulties of a separate infectious infirmary. A wing thrown off from the general infirmary for infectious cases, approached by a covered corridor well warmed and with through ventilation, along which the patient could be taken without risk, appears to us the most workable scheme for a school infirmary, and we know it to have answered well over a number of years where it has been fairly put to the test.

The clause providing that a master in whose house infectious illness has arisen should undergo thorough personal disinfection before resuming work in school is a wise though stringent rule, but we cannot help remarking how much it is in contrast with what the medical officers think necessary in their own case, which is to consist apparently of putting on a large mackintosh before entering an infectious ward. The stringent rule laid down for the master, if necessary in his case, is equally so in that of the medical officer, and should be as rigorously observed.

Some difference of opinion prevailed as to the period of quarantine after exposure to scarlet fever. Dr. CLEMENT DUKES suggested eight days, Dr. FERGUS seventeen days. The Association ultimately adopted by resolution fourteen days. We make no doubt Dr. FERGUS could give many instances of the development of scarlet fever after fifteen days' exposure to infection. We have known instances of such, and we think his suggestion should have been adopted by the Association, or even a longer period than he suggested. The question, When may a pupil who has had scarlet fever safely go home or rejoin school? we think to have ended in a somewhat lax resolution. It would have been better if the resolution had more fully recognised the fact that completion of desquamation may vary from the third to the twelfth week, and that no case can be regarded as sufficiently free from infection till at least a fortnight after desquamation has been entirely completed.

ALTHOUGH certain differences in practice still prevail among surgeons, yet it may be safely asserted that the comparative value of the varied methods of amputation is generally and justly appreciated, and the differences which exist are all explicable by the fact that the perceptions of varied minds always differ to some extent. The value of the so-called "subperiosteal" method of amputation has, however, excited far less attention in this country than on the Continent, or than it really merits. It is now seventy years since WALTHER of Landshut published a short note on this subject, and since then such well known men as OLLIER, TRÉLAT, PONCET, ESMARCH, and VOLKMANN have experimented upon it, practised it and written in its favour; while many other names less familiar to English surgeons have contributed to the literature of the subject. The procedure is not described in our English text-books and Systems of Surgery, and when the late Mr. SHUTER showed a patient upon whom he had performed subperiosteal exarticulation at the hip-joint at the Clinical Society of London, it was regarded by not a few as almost a new departure in operative surgery. We cannot doubt that, both in this country and in America, some surgeons have adopted this modification of the flap or circular method of amputation, but it certainly is by no means generally practised, or even recognised.

It may be well, therefore, to explain what the method is, and how it is best carried out, before entering upon a consideration of its merits. The special feature of the method consists in detaching a flap of periosteum from the portion of bone to be removed, sufficient to cover over the sawn end of the bone. The connexions of this periosteal flap with the muscles on its outer surface must be carefully preserved, that there may be no interference with its nutrition; and to counteract its tendency to retract with the muscles, its cut edges should be united by fine catgut, and great care be taken to secure rest to the stump by suitable compression. The detached periosteum should equal in length the diameter of the bone at the point of section, and the amputation flaps should be cut so that their base is this distance below the line of amputation; then when they have been reflected up to their base, the periosteum should be divided circularly round the bone, and detached by means of an elevator or raspatory.

The advantages that may be claimed for this mode of amputating are: First, that the sawn surface of the bone is brought into contact with the tissue which is physiologically fitted for its protection, and to which it becomes organically united most quickly and certainly; while, if the operation be carefully done, no part of the bone is bared of periosteum, and its vitality thereby endangered. Secondly, that from the periosteal flap a thick layer of new bone is quickly developed, which securely closes in the medullary cavity; by this and the rapid primary adhesion of the periosteal flap, the medulla of the bone is guarded against the spread of any inflammation or suppuration that may be present in the soft parts of the stump. Thirdly, that the stump is a better one than can be guaranteed by any other method, as there is no tendency for the bone to adhere to the cicatrix, and little if any liability of the bone to atrophy; the stump is firm, and the soft parts over it are mobile and supple. These are distinct advantages. But what can be said on the other side of the question? First, that when flaps are well devised and made, and the wound properly treated, a mobile stump without adhesion of the bone to the cicatrix is obtained. Secondly, that muscle will adhere to the sawn end of a bone, and that in such a case the medullary canal becomes closed in by a plate of osseous tissue; this lamella is, however, much thinner and of later formation than when a periosteal flap is made. Thirdly, that to detach and suture this flap of periosteum adds to some extent to the duration and difficulty of the operation. In the large majority of cases this objection should have no weight. As M. NICAISE points out in the current number of the *Revue de Chirurgie*, we have arrived at a period in the progress of surgery in which it is incumbent to study how, by attention to small details, we may give our patients the most useful stumps, for the more important measures by which the operation of amputation has been deprived of its chief dangers are known and practised with more or less success by all surgeons. Fourthly, in young persons the preservation of a flap of periosteum may lead to an osteophytic outgrowth from and around the bone. The liability to this greatly lessens after adolescence. But it seems clear that it only occurs when there is inflammation of the tissues of the stump or some abiding irritation of the osteogenetic tissues of the periosteum. And now that we

are able, in the great majority of cases, to exclude these processes with an approach to absolute certainty, this disadvantage is not of great moment.

These we believe are the arguments that may be advanced for and against this method of amputation. We cannot but think that, when carefully considered, they show a distinct balance in favour of the operation, and we hope that British surgeons will devote more attention to it than heretofore, and that we shall learn from them the results they obtain.

Annotations.

"Ne quid nimis."

LUNACY LAW REFORM.

WE must be excused for taking as much note of the medico-social aspect of the lunacy question as of that which may be more properly called its "professional" aspect. Regarded from the first-mentioned of these points of view, it must be confessed that it does not strike us as an impending calamity that "we are now within a very reasonable distance, indeed, of a strike among medical men against signing lunacy certificates at all." We do not quite know what "a very reasonable distance" may mean, though we have a fairly distinct notion of what "a measurable distance" —Mr. Gladstone's favourite phrase—signifies. However, the distance is not the most interesting feature of the case. So far from a general refusal to sign certificates being a calamity, we venture to think it would be a blessing to the community and to the profession. Matters would then, doubtless, be placed on a reasonable basis as regards the purely medical function of diagnosing mental disease distinguished from the absolutely non-medical, if not anti-medical, business of keeping private prisons for the incarceration of certified lunatics. It is most devoutly to be hoped that we are within "a very reasonable distance" of the auspicious moment when the Government may be ready to propose, and the Legislature find leisure to consider and pass, a short measure putting an end to certificates altogether. It is a most unreasonable procedure to certify a lunatic. The law blindly exacts certificates, and medical men give them, but both the command and the compliance are unreasonable and needless. By all means let us "strike," and rest assured good will come of it, though not perhaps precisely in the way some persons expect.

CEREBRAL PATHOLOGY.

AT the last meeting of the Clinical Society a paper was read by Dr. Hale White on lesions of the frontal lobes. It is a matter of surprise, considering the freedom with which such questions have been discussed, that so much yet remains to be learnt. Has it not been accepted as a fact for some time past that injury to or disease of one of the frontal lobes is unattended with important damage of the ordinary functions of mental life? Whether this absence of symptoms is due to insufficiency of examination or not seems to be a matter worthy of consideration. Another possible view of the case is to suppose that in the recorded cases the individuals injured in the frontal regions have not been of the educated sort, and that as a consequence the functions which should have been present have never been developed. It seems certain that this kind of explanation would hold good for many cases of absence of symptoms when we have to deal with infants and others whose mental powers have not yet appeared, for the all-sufficient reason that the structures which entitle them to the possession of the faculties are then in an immature condition. Moreover, it would appear that Hartley's time-honoured distinction between volitional and automatic actions is greatly in danger of being forgotten, or at least of being misunderstood. We should have thought that no one would have cavilled at Mr. V. Horsley's statement that the drawing of a triangular outline with one hand whilst the other was describing a circle was an impossible performance of consciousness. Consciousness is single and undivided, as best seen in close attention. But there are such processes as may safely be called subconscious, or almost unconscious, and amongst these must be classed the performances of telegraph-clerks, weavers, and interpreters of music, whether of the Chopin order or not. It is not uninteresting to consider how far education would be possible in the absence of that most important principle which shows that volitional acts do, after a series of performances, become automatous, requiring very little or almost no guidance from the highest intellectual centres. The last meeting of the Clinical Society might not unreasonably be called a psychological evening, for both Dr. Hale White and Mr. Victor Horsley made the paper which the former read the occasion for some general remarks on the psychological functions of the cerebral cortex, if such a mode of expression, where mind and matter are confused together, be allowed. The latter gentleman is a supporter of the view that the highest intellectual functions are mostly energised from the hinder portions of the brain, whilst the frontal regions are the special seats of the highest emotional faculties, including, as we understood him, the power of giving expression to these. The lines of Hamlet, "See what a grace was seated on this brow: Hyperion's curls; the front of Jove himself!" would on this showing not be testimony to the intellectual faculties of the Queen of Denmark's first consort. However, the time has not yet arrived when we can speak with certainty on such matters, though it is clear from Prof. Ferrier's experiments and many clinical observations that the perceptive functions associated with the most intellectual organs of sense, the visual and auditory, are represented in the posterior regions of the cerebral hemispheres. The view which Dr. Hale White propounded with regard to the most recently acquired faculties as having no very definite site in the cerebral cortex, so that either frontal lobe may assume the functions of the other, would appear to have some kind of connexion to the views of evolution and dissolution as propounded by Dr. Hughlings Jackson. Though it is usually taught that function precedes structure, yet there are many considerations which lend support to the notion that these elements go hand in hand. On this view it is not difficult to understand how, so to speak, virgin brain soil may be made by education to perform any functions whatsoever. True it is that through a long series of ages certain specialisations have already been effected, and the development of the individual must on the laws of evolution proceed along the lines which heredity has laid down—that ontogenesis must be rapid phylogenesis. But, potent as are the influences of untold generations of experience, still the present agencies are in a measure perhaps more powerful.

SCURVY.

WE have received by this mail an interesting paper by Brigade Surgeon Cameron Macdowall, containing a criticism on the new theories and experiences of scurvy, which was read before the Bombay Medical and Physical Society. Dr. Macdowall criticises Mr. Neale's experience as to the value of fresh meat as an antiscorbutic, and he also controverts the statement that certain of the Hill tribes live altogether without vegetables and yet are free from scurvy. He says that undoubtedly these do make use of vegetables, and also cases of scurvy do occur among them. Dr. Macdowall very properly insists that nothing should be allowed to supersede the use of fresh vegetables, or the administration of lime-juice to troops and sailors during

campaigns or long voyages, when vegetables cannot be obtained. Still we cannot agree with him in his depreciation of fresh meat rations as a prophylactic. Experience has also shown that too much reliance must not be placed on preserved vegetables, the crews of the whaling vessels, who are supplied freely with the Dutch preserved vegetables, which are generally admitted to be the best, often being severely visited with scurvy. It is probable that the antiscorbutic value of vegetables and meat depends on the freshness of these articles, and that by keeping changes occur which diminish this value. The nature of these alterations probably are very similar to those that take place in the saccharine elements, as we see in fodder preserved by ensilage, in which there is an increase of free organic acid, whilst the amount of alkaline bases present remains the same. He has moreover shown that in scurvy the amount of alkaline phosphates discharged by the urine are diminished, a fact subsequently confirmed by Zuelzer, and this he considers a proof that in this disease the alkalinity of the blood is diminished, and that the alkaline phosphates are consequently retained in the system to supply the deficiency. This view is supported by the experimental researches of Hoffmann and Loscar, both of whom found that the organism retained its alkaline bases when an attempt was made to reduce the alkalinity of the blood; and Dr. Macdowall is in error in supposing that it is based on Maly's researches, since on the question of the derivation of acid from the alkaline blood, in the case of urine, Maly and Ralfe distinctly differ.

THE SANITARY INQUIRY IN CALCUTTA.

WE regret to learn from the Indian papers that there has been an occurrence of an unpleasant character in the proceedings of the committee appointed by the Lieutenant-Governor to inquire into the manner in which the cleansing and conservancy of Calcutta have been carried out, and to report what further provision should be made with a view to increased efficiency. It appears that Surgeon-General Payne was requested by the committee to attend to give evidence; that in the course of his examination certain questions were put to him by Mr. Cotton, the member nominated by the municipal commissioners, which Mr. Beverley, the chairman of the committee, considered to be of "such an offensive character that Dr. Payne very properly declined to answer them." Mr. Beverley felt himself called upon to address a letter to the chairman of the corporation protesting in very strong terms against the course taken by Mr. Cotton, and this, with Mr. Cotton's reply, has been published in the papers. No report of the questions put has reached us, and we therefore refrain from giving any opinion on them, except that we cannot conceive an officer of Surgeon-General Payne's high character refusing to answer them without good cause; nor a gentleman of Mr. Beverley's social and official standing protesting in the strongest terms against Mr. Cotton's conduct in putting them, unless they were most objectionable. It appears from the correspondence that Mr. Cotton was coached up on these questions by Mr. Harrison, the chairman of the municipal commission, and that they were "intended to show Dr. Payne's hostility to the elementary principles of local self-government." This did not form any part of the question referred to the committee for report, and the effect of its introduction must have been, whether intentionally or not, to divert attention from the important subjects under investigation, and to mix up personal matters with questions of great public interest. Unless Mr. Cotton can show that he adopted the course which has given rise to so much unpleasantness in the interests of the Calcutta public, and not of the municipal corporation as distinct from this, he has laid himself open to severe reprehension, and has done much to damage the reputation of the body which he represents on the committee. We have every confidence that Sir Rivers Thompson will not allow himself to be influenced by this occurrence, but that he will carry out fearlessly and impartially the investigation into the working of the sanitary commission. In the mean time this method of raising an issue quite distinct from the question referred to the committee cannot fail to excite distrust, on the part of the public, in those by whom it has been adopted, and a suspicion that there is good reason for wishing to divert attention from the subject under investigation.

PROPOSED ENLARGEMENT OF THE ROYAL SURREY COUNTY HOSPITAL.

A SPECIAL meeting of the Court of Governors of this excellent and very necessary institution, held last week in the board-room of the hospital, was hardly, we should hope, needed to enforce its claim upon the attention of the wealthy and charitable county of Surrey at a time when it is obvious that it cannot adequately meet the demands made upon its space and resources. None the less, however, are we glad to see a long account of this meeting in the *Surrey Advertiser*, since it is only, too frequently, that by "bold advertisement" alone kindly hearts are impressed with the necessity for open-handed generosity. "Evil is wrought by want of thought as well as by want of heart," and good often slumbers for want of initiation. In this case excellent examples are not wanting. It was announced that the Earl of Onslow had generously offered land to the value of £1000 for £600, and supplemented it by a gift towards the expenses of £300. Mr. J. S. Budgett of Stoke-park, who very properly deprecated the selling of stock unless absolutely necessary, and pointed out that "to hesitate to believe that the county would contribute £5000 was an absurd and timid policy," also promised a contribution of £250 and £10 a year towards the increased amount that would be required annually to support the extension. It is also stated that before the governors left the room the list of subscriptions had nearly reached £1000. The Royal Surrey County Hospital has now to cope with a remarkable increase in the number of patients, and to provide for the wants of an extended area, therefore we are convinced that the committee being able to purchase the required land at once, though the building is not to be commenced until at least half the estimated cost (£6000) of the new wing is promised, the inhabitants of the county will promptly ensure not only a start, but the whole of the required sum by contributing of their abundance, of their sufficiency, and, we venture to hope, even of their mites. It is proposed to include in the intended additional accommodation separate wards for children.

AVOIDABLE ILLNESSES.

IF men were to reflect upon the amount of illness, not to mention other evils, which they bring upon themselves, a total which ever increases with their self-development in civilisation, they would sometimes question the reality of a progress which includes so many errors. Even if we leave out of sight the known results of faulty practice, there is still a large margin of what seem to be anomalous mishaps which day by day are shown to have had an acquired and avoidable beginning. It is always satisfactory to get at the root of these unaccountable flaws, especially when they nearly concern one's personal health. Their removal is then usually assured, and our former discomfort or dread is covered with the satisfaction of enlightenment and of remedial success. Trade-work has at all times illustrated, and does still continually illustrate, the truth of these remarks. Let us grant all that is due to its energy and enterprise, and still

the value of its productions is heavily discounted by errors which are not only due to oversight or ignorance but often to neglect. In so far everyone will admit the need of correction. By way of example, consider the case of staining and its applications. We showed a short time ago that some of the aniline dyes in the market, from whatever reason, were found to possess poisonous properties and to be unfit for dyeing articles of dress. Further evidence has not been wanting to confirm those observations. Another and older enemy of health, arsenic, has never been extirpated, but shows its front among us from time to time. Cases of poisoning by arsenical wall papers have been reported quite recently. The symptoms described, it is true, did not include the gravest possibilities, but chronic and intermittent ill health was proved to depend upon the presence of a highly coloured paper containing much arsenic. Mere colour we would add, however, is no test of quality in this respect. The most innocent-looking hues may be arsenical, and, conversely, the same tints may be had without any such poisonous admixture. Undoubtedly the only guarantee for safety is to be found in the discontinuance of this or other similarly hurtful substances as dyes in dwelling-houses. While there is any doubt about the matter, no custom in decoration can be safer or better than that of distempering walls and afterwards oil-painting them with some plain colour.

THE DWELLINGS OF THE PEOPLE.

AT a meeting of the Mansion House Council on the Dwellings of the People, held on Friday, January 9th, many matters bearing on the cleanliness and health of the London population were brought forward and discussed. Reference was made to valuable work done by the agents of the Council in educating the inhabitants of poor districts in sanitary usages by means of handbills and lectures on the subject. Important suggestions were also offered on certain points in which the law was still imperfect or inactive. Such were the removal of nuisances and of household dust, and the system of water-supply, the election of medical officers of health, the control of vestries and of house-holding vestrymen, the notification of infectious disease, the registration of house owners or lessees and of the inmates of tenements, the erection of mortuaries where necessary, the encouragement of sanitary officers in regard to salary, &c., and the protection in case of legal process of district surveyors of buildings. A report embodying the above-mentioned proposals was submitted to the meeting and adopted unopposed. Further suggestions relating to plans for cheapening house rents, and for thinning the civic population by building suburban dwellings, likewise received favourable consideration. Regarding the importance of each and all of the plans of reform described on this occasion, there can be no question. The Council have done well to signify their general agreement to them. There must, of course, remain among so many resolutions, matters of detail which call for thoughtful discussion, and perhaps for modification; but their gist, as they stand, is such as the medical profession as a body will not scruple to approve. The proposed measures of cleanliness, the removal of refuse, and the maintenance of water-supply, cannot fail to influence to the best purpose the great nest of contagion which exists in our midst. The notification of infectious cases is a not less important subject. The theory on which it rests is a principle in medical science. Sense and judgment in its application may render it a most serviceable aid in practice, and we hope that the want of these may not be suffered, as in some past instances, to mar its utility. The recommendations of the Council with respect to registration of ownership and of tenants must command our warm support. Indeed, without some system of the kind reform is hopeless. We cannot conclude these remarks without endorsing the statements made in favour of improving the standing, remuneration, and security of inspectors and district surveyors. Apart from the personal risks and expense which such men are liable to incur, there is much to dissuade and discourage them from the conscientious discharge of their duties. There is, therefore, the more reason why the authorities and the public should choose trustworthy men for such offices and should grudge them in their exercise no requisite facilities.

ADMINISTRATION OF THE DARENTH SMALL-POX CAMP.

THE complaints of bad administration at the Darenth Small-pox Camp have assumed a much more serious aspect since Mr. Nathan Robinson, himself one of the committee charged to see to the efficient working of the camp, made admissions at a recent meeting of the St. Pancras Vestry which at first sight go far to prove the case of the complainants, and we are glad to see that such an inquiry as we advocated last week is about to take place into the circumstances which have been brought under public notice. Briefly stated, the charges which have been made relate to the inferior quality of food, difficulty in securing regular meals, enforced labour beyond the strength of the patients, failure to supply sufficient clean linen, want of proper classification of patients, &c. On the other hand, Sir Edmund Currie, whose voluntary and incessant labours in connexion with the preparation of the camp and hospital ships at a time of great emergency are deserving of the highest recognition, both on the part of the managers of the Asylums Board and of the public, repeats his statement that some of the allegations made are absolutely untrue; also we publish in another column a letter by Surgeon-Major Ince in which strong testimony, as the result of a minute personal inspection, is given to the present satisfactory condition and arrangements of the asylum. We have always looked upon the huge aggregation of patients at Darenth as calculated to bring about administrative difficulties even of a more serious kind than those which are alleged to have taken place; and quite apart from the truthfulness or otherwise of the complaints, we think that good is certain to result from any sufficiently exhaustive inquiry that may be made.

ISOLATION IN GREATER LIVERPOOL.

THE city of Liverpool having at last provided itself with hospital accommodation, though of a limited and temporary sort, the Greater Liverpool which surrounds the borough finds itself in much the same sort of trouble as that which the parent city suffered from. The Toxteth-park Local Board of Health cannot but have known that the arrangement hitherto adopted, by which people have been pauperised for the sake of the protection of the public health, must come to an end; but apparently they have failed to act under the powers which they, as a sanitary authority, possess to provide suitable means of isolation for their district. The result has been that on the occurrence of some recent cases of small-pox they had to run hither and thither pleading with workhouse and sanitary authority to aid them in an emergency which should have been foreseen and provided against. For some considerable time they met with nothing but stern refusals; the city hospital was solely for Liverpool citizens, and the use of the workhouse as an infectious hospital had been prohibited by the Local Government Board. At last, however, this prohibition was disregarded, and once more Toxteth-park saves itself from some danger at the expense of pauperising some of its inhabitants. It is to be hoped that the lesson which has again been taught will not be allowed to pass unheeded. When the authority last met they decided to

find out if other sanitary bodies would co-operate with them in the matter of hospital provision. Whether by combination or otherwise, the Toxteth-park Local Board have a duty to perform to the inhabitants of their district, and they should forthwith take measures to make such hospital provision as is adapted to their special needs. Other sanitary districts which go to make up the Greater Liverpool would also do well to take warning in time.

HARMLESS LUNATICS TO BE SENT BACK TO THE WORKHOUSES.

IT is amusing to observe the irony of Father Time in his dealing with questions of socio-political reform. By the familiar statute known by the name of its framer as the Gathorne Hardy Act harmless lunatics were to be rescued from the neglect and tyranny of workhouse-management and brought under the benign influence of the asylum system. So much was this desired that, in addition to providing large establishments for the reception of imbeciles, four shillings a head was allowed per week for the maintenance of harmless lunatics in asylums. Under this inducement—until its illusory character was proved—the old women who would not get up, and the old men who would not go to bed, without more trouble than workhouse authorities cared or dared to expend on them were transferred to the asylums. Now they are to be sent back to the workhouses, in order, as it is thought, to make way for non-paupers in public asylums. In so far as this may be a clumsy step towards the abolition of private asylums, we hail the token of awakening; but we are not so very sure that the new move will be in the direction supposed. This may only be another of many devices for the providing of asylum accommodation adequate to the needs of a population which is increasing chiefly, if not wholly, because it is being rapidly multiplied by fanciful definitions of "insanity," and because the difference between *increase* and *accumulation* is not even yet adequately understood.

CHOLERA IN INDIA.

IN a short annotation in THE LANCET of October 4th, 1884, attention was drawn to the prolonged duration of cholera in the Tanjore circle. The sanitary commissioner of Madras (Dr. Furnell) attributed it to the deficient and contaminated water-supply, and predicted it would be considerably lessened as soon as a proper monsoon had filled and cleaned the tanks and watercourses. This prediction has been fulfilled. The south-west monsoon, which had held off during the months in which it usually makes its appearance—viz., June and July—came down late in August and September, and the mortality fell immediately from hundreds to tens per diem until the cholera disappeared entirely. Another very instructive example of the intimate connexion between a contaminated water-supply and cholera has recently shown itself in Madras town. A severe cyclone burst over Madras on November 21st, causing immense damage to houses, trees, and standing crops; but, greatest misfortune of all, causing a breach in the bund of the Red Hills tank or lake from which Madras is supplied with drinking water. The water from this immense reservoir, quite a little lake, flooded the country round, carrying away several villages and causing great loss of property and life, and depriving 400,000 inhabitants of their usual supply of water for domestic purposes. Recourse was had immediately to the old and deserted tanks and wells which dot the town, but whose use had for many months past been given up under municipal authority. Up to the date of the breaching of the tank no deaths from cholera had been returned for the month within the municipal limits of Madras. Five days after the catastrophe—viz., on November 26th—two cases occurred, and from that date the cholera has increased, until at the present time of writing the deaths number some ten to fifteen a day. In the meantime strenuous efforts have been made under a strong committee appointed by Government to obtain a pure water-supply from other sources, and with such success that at the date of our information the stand-pipes had begun to give forth a moderate supply of good water. There is little doubt cholera will again rapidly disappear.

THE REGISTRAR-GENERAL'S WEEKLY RETURNS FOR 1885.

THE area embraced by the Registrar-General's weekly returns during 1885 will be the same as it was last year—namely, the twenty-eight large English towns and the outer ring of suburban districts around London. The population of these towns, including the London suburbs, in the middle of this year is estimated at 10,021,684 persons, showing an increase of 184,696 upon the estimate for the middle of 1884. The population of London and its suburbs is estimated at 5,199,166, or more than 100,000 in excess of the estimate for last year; the increase of population of inner or registration London being 64,567, and of the outer ring 40,604. The largest of the provincial towns are Liverpool with 579,724 persons, Birmingham with 427,769, Manchester with 337,342, and Leeds with 333,139. Manchester with Salford would take third place with a population of 541,417, very little less than that of Liverpool. The smallest towns in the list are Huddersfield, 87,327; Wolverhampton, 79,185; Halifax, 77,378; and Plymouth, 76,045. The weekly returns also include statistics of Edinburgh, Glasgow, and Dublin, furnished by the Registrar-Generals of Scotland and Ireland, the aggregate population of these three cities being rather more than a million. And, lastly, the returns give certain information for thirty-three colonial and foreign cities supplied by various authorities abroad, the estimated aggregate population of these cities exceeding sixteen millions. Thus the Registrar-General's weekly returns for 1885 will give mortality statistics for populations at home and abroad amounting in the aggregate to more than twenty-seven millions of persons. It may be noted that the list of twenty-eight English towns specially dealt with in the returns includes all towns in England and Wales that had at the time of the last census a population exceeding 70,000 persons; the only exceptions being Croydon and West Ham, both of which lie within the compass of the outer ring of London.

"SINGULAR MEDICAL ACTION."

THE *Islington Gazette* reports under the above heading an action by Mr. John Walker Smythe, for the recovery of £2 13*s.* 6*d.* for professional services rendered, against a Mr. Pond. The charge was for attendance on the defendant's wife. The defendant filed a counter-claim of £4 for expenses incurred—so it was alleged—as a consequence of the plaintiff's negligence. The patient, according to the plaintiff, suffered from "injuries caused by her husband" and bronchitis. The defendant suggested another opinion, and Mr. Weston was called in. An abscess formed, and an attempt was made to show that by ordering cold water applications Mr. Smythe had treated it wrongly, as also by lancing it in the wrong place and at the wrong time. Mr. Smythe, thinking the nurse negligent of his instructions, retired from the case. Nothing was heard of the defendant's complaints till the bill was sent in. The attempt to show serious difference of opinion and practice between the medical men broke down completely, and the judge, after some very sensible remarks, gave a verdict for the plaintiff on both claim and counter-claim, with costs.

THE CLINICAL SOCIETY.

THE annual general meeting of this Society was the occasion for the reading of the Report of the Council and the Treasurer, which showed that the Society was in a prosperous state and numbered nearly 400 members. The Society had to regret the loss by death of Dr. Hall Davis, Dr. Barclay, Dr. Mahomed, Mr. Cæsar Hawkins, Professor S. Gross, and Mr. Wheatley. The exhibition of living specimens had been carried out on an increasing scale during the past year. Myxœdema, spina bifida, and Charcot's disease had been the subject of special work. Dr. Frederick Taylor proposed, and Dr. D. W. Finlay seconded, that the Report of the Council be received, adopted, and published in the Society's Transactions. Dr. Moxon proposed a vote of thanks to the retiring President, Sir Andrew Clark. He said that as he went away from the discussion the other night he was wondering what in other professions would correspond to the scene he had been witnessing, and he could not think of anything quite like it in the Law or in the Church. Perhaps in the Army and Navy there is something of the kind. He had heard and read very interesting discussions in connexion with these services in which our national dangers and defences have been considered. But at these important debates the Secretary of State for War was not to be seen nor the First Lord of the Admiralty. He congratulated the profession that its leaders were found able and willing to preside over Societies like the Clinical. The members were not, said Dr. Moxon, insensible of the sacrifice which is thus made for our benefit when time of such value is spent amongst us. Sir Andrew Clark had supported the clinical character of the Clinical Society. It was a great pleasure to propose a vote of thanks to the retiring President. He remembered proposing not many nights ago another vote of thanks in the Society, and if the Society would allow him he would like to allude to that occasion, because, largely through the chairman's courtesy to him, he was allowed to take up a somewhat ambiguous position, which led to his expressing his admiration of Professor Charcot under circumstances that seem to have prevented the earnestness and reality of that admiration from appearing clear to those who only read the report of what he said. He would now like to be allowed to say, with perfect distinctness, what he intended to have said on the former occasion, and to express his full recognition of the great advantages which the work of Professor Charcot had conferred on the medical profession, and the brilliantly successful manner in which he has thrown light on many obscure problems. Returning from this digression, he would again ask the Society to express warmly its thanks to Sir Andrew Clark. The vote of thanks was passed by acclamation. The list of officers for the ensuing year was published in THE LANCET of Dec. 27th, 1884.

A CONVENIENT MODE OF INQUIRY.

THE Education Department is, in a praiseworthy way, setting an example of ingenuity to other departments throughout the country. The allegations of over-pressure recently made are being specifically investigated. The inquiries already instituted have been, so far as we can see, carried out in a very careful and exemplary manner, and what makes them particularly valuable is the fact that they were conducted either by the managers of schools themselves or by the inspectors; in short, by one or other, or both, of the parties upon whom the responsibility of wrong-doing or neglect, if proved, must have fallen. This is an admirably simple and promising idea. We hope to see it extended. Instead of all the fuss and trouble of proceedings at Scotland-yard and at assizes, why not refer the whole business of criminal investigation and the repression of crime to the criminal classes themselves, who might be asked to form themselves into a standing committee of inquiry? Thus with all matters of management: let asylums for lunatics be inspected by their own committees; factories by their proprietors; let London milkmen analyse the milk; and so on. The reports obtained from these sources will be just as interesting and of precisely the same value as that which has just been furnished to the Board.

TUBERCULOSIS IN LARGE RUMINANTS.

TUBERCULAR inoculations in large animals have been but little practised, though they would appear to possess special interest for the pathologist. The progress of events in the lymphatic system and distant viscera may be watched more easily than in smaller animals. M. Colin has worked at this subject. His method is to introduce beneath the skin a drop of pulp with a thin section of tubercle taken from an animal recently killed. A tumour rapidly develops at the site of inoculation and opens towards the end of the second week; the orifice grows larger from ulceration, and a sort of gaping chasm is formed, with cheesy contents, having much resemblance to the cavities in the lung. Numerous grey granulations form in the wall around. At the same time the nearest lymphatic gland becomes swollen and tubercular, either as a whole or at several parts. The whole of the morbid process may subside after it has reached this stage, the viscera and remaining lymphatic structures not being affected. These local processes take place without any fever or wasting. In young animals the tendency to tuberculisation is much greater, and then the dissemination of the tubercle may be followed all along the lymphatic vessels into the thoracic duct, and finally over the different viscera, including the serous membranes. The periods of incubation and of spread to the viscera have been carefully worked out, but the report from which we take the above abstract is wanting in details.

PREVENTIVE MEDICINE IN SCHOOLS.

WE pointed out in an annotation last week that the teeth of all the children attending the communal schools in Brussels are examined by order of the State, and that during the year 1882-83 no fewer than 1250 pupils required the services of the dentists, which they would probably have never otherwise obtained. We are glad to note in this connexion that the managers of the North Surrey District School, Anerley, acting on the advice of the medical officer of the school, Mr. H. J. Prangley, have appointed a dentist to attend weekly in order that the children may have proper attention paid to their teeth. The managers and Mr. Prangley are to be congratulated on the important step they have taken. There can be no doubt that the appointment will receive the sanction, if it has not already been given, of the Local Government Board.

THE CAUSE OF SOOT-CLOUDS.

STRIPPED of its technicalities and reduced to the common-sense level of average human brain-power, the discussion about soot and fuel economisers amounts to this: We want less of force and rapidity and more of volume in the air passing through our domestic fire-places. They ought not to be so much like small blast-furnaces as they too generally are. The fuel, whatever it be, should burn quietly, consuming the combustible part of the fuel, allowing the gases—which are partly waste, unfortunately, and partly consumed—to rise slowly and passively and escape up the chimney without blowing up the residue of the carbon with them. A strong and rapid current of air through a fire must mean waste, and most probably will also mean soot or smoke. The air

which supplies oxygen to a fire should be wafted gently between and over the coals in the grate, not blown with a rush from below through them. If this simple fact be mastered, it will be easy to secure the object with almost any grate and any fuel. If it be not understood, the search for a special apparatus and particularly good fuel must be futile. Let us begin by first learning and then teaching the A B C of the process, which is really very simple if it be only understood. As it is, the cloud of words is becoming almost as great a nuisance as the soot-cloud itself.

THRUSTON PRIZE, CAMBRIDGE.

THE Thruston Prize of fifty guineas, which is awarded triennially to that graduate of Caius College who has published within the preceding three years the best original investigation in physiology, pathology, or practice of medicine, has just been adjudged to Dr. C. H. Ralfe, assistant physician to the London Hospital, for his researches in Urinary Pathology and Therapeutics. Communications giving the details of his researches have appeared from time to time in THE LANCET. In 1882 Dr. Ralfe collected these together, and published them in the form of a treatise, entitled "Morbid Conditions of the Urine dependent upon Derangements of Digestion," and it is for this work that the committee appointed by the College to decide the prize have made their award. This is the first time the prize has been bestowed under the new regulations of the recent University Commission. Formerly it was given annually, and was of the value of £18; it was in the gift of the Fellows, and was generally bestowed in rotation among the Doctors of Medicine, without any special work being required except a short address to be delivered by the recipient in the College chapel. The present arrangement is undoubtedly an advance in the right direction, since the element of competition greatly increases the value to the recipient; whilst the requirement of "publication" permits of criticism and comment on the work done.

CERTIFICATES IN LUNACY.

IN his annual report on the Metropolitan Imbecile Asylum at Caterham, Dr. Stanley Elliot refers to the inadequate material on which patients are at times consigned to asylums. Thus, in one case the information supplied by the medical practitioner was as follows: "Very subject to epileptic fits, which prevent his doing any work." It is added, as regards this patient, that he was undoubtedly of unsound mind; but Dr. Elliot expresses an opinion, in which all unbiassed persons will concur, that, in the interests of the liberty of the subject, no individual should be consigned to an asylum for the insane unless facts actually indicative of insanity are recorded by those who venture to sign certificates. We can only wonder that such a certificate as the one just referred to was allowed to remain in force.

REMOVAL OF ARTIFICIAL TEETH FROM THE ŒSOPHAGUS.

ON Wednesday, the 14th inst., a patient was admitted into the Middlesex Hospital having just accidentally swallowed a plate with four artificial front teeth. Mr. Lawson saw the patient and endeavoured to extract them with long forceps; but finding that, although he could feel them, they were so low down that he could not seize them, he decided to open the œsophagus. This he did, and removed the teeth. The plate was lodged in the œsophagus below the level of the cricoid cartilage, and was fixed by the sharp points of the clips which held it to the other teeth. The patient is making a satisfactory recovery.

SWISS DRUNKENNESS AND THAT OF OTHER COUNTRIES.

The Times continues its interesting series of communications on the drink question in Switzerland, which should be carefully read by public and philanthropic men in all the countries of Europe. The present communication consists of an analysis of the report of an inquiry into the whole subject by the Federal Council, which seems to have been carried out with great ability, and is supplemented by a report from Dr. Schuler, Federal Factory Inspector. The consumption of spirits, and, still worse, that of absinthe, has "portentously" increased. The increase of spirits has been much faster than that of wines, though the importation of wines has quadrupled in little more than thirty years. The greatest rate of increase of both was in the period of prosperity including and following that of the Franco-German war. The Federal Council attribute this most disastrous increase in the consumption of alcohol to two causes: first and mainly, to the introduction of free trade in alcoholic beverages, and the withdrawal from the Cantons (by the Constitution of 1874) of the power to limit public-houses; and secondly, and in great measure, to the commercial and agricultural prosperity which prevailed some ten years since. "Good times make drinking" in Switzerland as elsewhere. Spirits are very cheap; in the Canton of Berne two decilitres of schnapps (containing 6 oz. 8 oz.) may be bought for one penny—almost as cheaply as beer. The result in the production of pauperism, crime, insanity, physical incapacity, and death is told in the article. It is the disgrace of England to show more coarse drunkenness than most other countries, but in the amount of alcohol per head consumed she is exceeded. A table is given showing that this amount is greatest in the following countries in the order of their names: France, Belgium, Switzerland, Denmark, England, Germany. Assuming that spirits contain 50 per cent. of alcohol, wine 12½ per cent., and beer 5 per cent., the Frenchman's consumption of alcohol is at the rate of 19·67 litres per year, that of the Englishman 10·03, and that of the Swiss 13·45; the Dane, though he consumes 18·90 litres of spirits in the year, drinks so little wine and beer that the actual alcohol which he imbibes is represented by 12·22; the German is a long way in the rear with 8·30 litres. The Frenchman drinks almost as much wine as the Englishman does beer; it contains twice as much alcohol; besides, he takes brandy in his coffee. The ordinary Englishman does not diffuse his drinking as the ordinary Frenchman does; he drinks one or two days a week to his great disgrace, and, let us hope, repents during the remainder. There is this further difference in England: the existence of large classes who drink nothing or next to nothing, leaving the still enormous consumption of alcohol in England to fall on those pitiable fools who think it a harmless if not a healthy thing, and supply the statistics of our gaols and workhouses.

COCAINE IN RECTAL SURGERY.

COCAINE seems destined to play an important part in the treatment of painful affections of the rectum and genito-urinary system. Dr. Bettelheim of Vienna reports the case of a man, aged seventy-four, who had well-marked anginal attacks, the result of atheroma of the aorta and ossification of the coronary arteries. For some time he had, in addition, complained of rectal and vesical tenesmus. Percussion over the bladder showed that it was not dilated, and rectal examination demonstrated the fact that the prostate was much enlarged and probably the cause of the trouble. Cacao butter suppositories were ordered, each containing half a grain of muriate of cocaine. One of these was introduced into the rectum at bedtime, and the patient slept

well, and was not troubled during the night. The beneficial effects were apparent the whole of the following day. The suppository was not given that evening, and the patient passed an uncomfortable, restless night. The next day another suppository was ordered, and acted as well as the first. From the promptness and efficacy of the cocaine in this case, a brilliant future may be anticipated for the alkaloid in this department of surgery. It is now being largely used in many of the London hospitals in the treatment of piles, fissure, and fistula.

A JAPANESE NATIVE VILLAGE IN LONDON.

AT Humphreys Hall, Albert Gate, is now to be seen a complete Japanese village erected and occupied by natives of Japan. A considerable number (about 100) of Japanese people, of various trades and professions, have been brought over to this country with the object of familiarising us with their social customs, arts, industries, amusements, and even their religion—at least so far as regards a Buddhist temple, containing genuine idols and attended by two Japanese priests, can afford an idea of its mysteries. In the shops and houses of the village Japanese artificers pursue their various callings, embroidering, fan-making, china-painting, metal-working, screen-painting, umbrella-making, shoe-making, &c. In a theatre attached to the village various performances are given, such as fencing, wrestling, dancing by Japanese girls to the music of a native orchestra, and juggling. The Exhibition is an interesting one, and well worth a visit. By the way, the Japanese have for some time shown their appreciation of English medical education by sending over students to our hospitals. Some years since, if we remember rightly, a Japanese gentleman was house-surgeon to, and held other appointments at, St. Thomas's Hospital. Mr. Tannaker Buhicrosan, the promoter and managing director of the Exhibition, intends to hand over the proceeds to his wife, a Japanese lady who, a Christian herself, intends to conduct a mission to Japan for the purpose of propagating Christianity in, and reforming the marriage laws of, her native country.

POISONED "SLEEP" AND DEATH.

ANOTHER sad case of "death by misadventure"—which phrase is rapidly coming to mean "poisoning with a narcotic"—draws attention to the folly of persisting in the refusal to treat sleeplessness as wakefulness. In this instance the victim was a member of our profession, Mr. Lionel John Shepherd, L.R.C.P., M.R.C.S., house surgeon at Poplar Hospital. The deceased had formed a habit of reading at night, and his over-taxed and weary brain could not sleep, so that Mr. Shepherd had recourse to narcotics. Taking an overdose accidentally, the poison did more mischief than simply stupefying him—its action was carried a little too far, and he died. The painful misadventure is much to be deplored; and not less is the course of treatment in which it occurred to be regretted also.

THE CASE OF THE CONVICT BRIGGS.

IN the *Grimsby News* of Jan. 2nd there is published a long letter from Dr. Ewing Whittle, criticising the medical evidence given at the trial of the husband of Thirza Briggs. We have already commented on this case. Dr. Whittle adduces other reasons in support of the theory of death from natural causes, to most of which we unhesitatingly subscribe. It is not necessary to give Dr. Whittle's argument in detail, considering, as we do, that more than enough has been elicited to warrant the Home Secretary ordering a full investigation of the case in its medical bearings.

TUBERCULAR INFECTION FROM SEXUAL CONNEXION.

IF tubercle be contagious, whether of bacillary origin or not, there is no reason why sexual connexion should not sometimes be the means of communicating the disease. But a clear proof of such an occurrence would be difficult to find, even were there no doubt of the nature of tubercle. Tubercle being contagious, the possible routes by which it infected would be so numerous that absolute demonstration could only be made in the experimental laboratory. M. Fernet, at a recent meeting of the Société Médicale des Hôpitaux, maintained that the infection of tubercle could take place either from the man or from the woman. The cases which he brought forward as substantiating his views were some in which the disease of the genitals was the most prominent, and probably the first lesion in the body, and in which the history showed that the tubercular disease began soon after sexual connexion with an individual the subject of tubercular disease of the genitals. Such a concurrence of events no doubt points strongly, though not conclusively, in the direction indicated by M. Fernet.

CERTIFICATION OF INFECTIOUS DISEASE AT HASTINGS.

THE medical profession at Hastings will do well to look narrowly to the new Bill which is proposed to confer additional powers on the Corporation of Hastings in regard to infectious cases. By one section of the Bill every medical practitioner attending such a case is forthwith to fill up, sign, and deliver or send to the medical officer, a certificate stating *the name of the patient, the situation of the building, the name of the occupier*, and the nature of the infectious disease. This is an intolerable burden to impose on medical men, even for the handsome remuneration of 3*s.* 6*d.* It ought to be resisted in every constitutional way. It is contrary to the public interest to convert busy and responsible medical men into clerks of the Corporation. We shall hope to hear of their united and determined opposition to making reports which should clearly come from the householder.

USE OF COCAINE IN LITHOTRITY.

WE understand that a lithotrity, with rapid evacuation of the fragments (Bigelow's operation), was performed under cocaine at the St. Peter's Hospital on Thursday last, with perfect success. The bladder was injected with half an ounce of a 4 per cent. solution of cocaine, and the operation was begun and completed *painlessly* in a quarter of an hour.

THE RELIGIOUS NEWSPAPERS AND QUACK ADVERTISEMENTS.

SOME of the best friends of religious newspapers, and even of missionary journals, are becoming seriously scandalised at the growth of the advertising of quack medicines in their columns. The feeling of disgust is not confined to the medical profession; nor, we must admit, is the scandal of quack advertisements confined to the class of papers in question. But the scandal is most striking and most unseemly in them. When a man sees in his religious newspaper an advertisement of a man or a medicine as pretending to cure a disease in his child or his wife beyond the bounds of the medical art, the pretension being backed perhaps by a great name, he is apt to yield to the temptation, and when the coarse pretension is refuted by the death of the patient he has a sense of injury. Such advertisements are questionable in any paper; but in those organs of the press which are supposed to represent "whatsoever things are

true" they are a positive offence. We appeal to our contemporaries to consider this representation, and to believe it made to them in no narrow professional spirit.

THE chairman of the Dundee Parochial Board at the monthly meeting on the 6th inst., replying to a deputation from the Aberdeen City Parochial Board on the subject of accommodation for pauper lunatics, stated that Dundee was in the same difficulty as Aberdeen in regard to finding accommodation for their lunatic poor; and after some discussion a committee was appointed to consider the matter. and if they saw fit to join the Aberdeen Board in a memorial to the Lord Advocate for an affirmation of the principle that parochial boards, if they consider it desirable, can build asylums of their own.

IT is with regret we have to record the death of Dr. William Rowlatt of Paris, at the early age of thirty-one. The melancholy event took place on Dec. 2nd last, during his voyage home from Australia in the *Melbourne*. Dr. Rowlatt was a young physician of great promise, and was an occasional contributor to our pages.

WE regret to have to record the death of Dr. H. T. Lanchester at his residence, Park House, Croydon, aged forty-seven. Dr. Lanchester, who was chairman of the Finance Committee of the Croydon School Board, and Physician to the General Hospital, was formerly in partnership with Dr. Alfred Carpenter.

THE Italian Senate after two days' debate adopted on the 11th inst., by 96 votes against 21, a Bill for improving the sanitary condition of Naples. A sum of 100,000,000 francs is to be expended during the next ten years upon the work, which will be carried out under the direction of the Government.

DR. E. BUCHANAN BAXTER, late Professor of Materia Medica and Therapeutics at King's College, and Physician to the Hospital, died on Wednesday last, after a prolonged and painful illness. We hope next week to publish a sketch of the life and work of this lamented physician.

THE discussion at the Royal Medical and Chirurgical Society on Dr. Kidd's paper on the Distribution of the Tubercle Bacilli in the Lesions of Phthisis has been adjourned to a special meeting of the Society, to be held on Wednesday, January 21st, at 8.30 P.M.

A LETTER of sympathy, signed by upwards of 200 of the principal residents of the village of Solihull, has, we learn, been presented to Dr. E. S. Page.

REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

[SECOND NOTICE.]

IT will be remembered that in the Report of the Medical Officer of the Local Government Board for 1882-83, Dr. Burdon Sanderson referred to the conditions under which spontaneous determination of the septic process took place, especially as the result of the coming into existence of chemical bodies in the liquid dealt with; the bodies in question being acids of the aromatic group. Dr. Buchanan also stated that, in connexion with researches which he had organised as to disinfectants, sustained work would be commenced with a view of ascertaining the behaviour of some better known contagia in presence of various colytic agents. Dr. Sanderson, in the recently issued report, gives the results of further experiments in connexion with this subject, and referring to phenyl-propionic and phenyl-acetic acids—aromatic acids of the acetic series—he states that they are both superior to carbolic acid in their influence of rendering a cultivation liquid unfit for the growth of bacteria, and that of the two phenyl-propionic acid is the more active. Dr. Klein, who has been associated with Dr. Sanderson in this work, has now inquired into their value as disinfectants, and Dr. Sanderson summarises the conclusions arrived at by explaining that although both bodies possess to a very marked degree the power of killing morbific microphytes, the higher of the two acids, phenyl-propionic acid, has been found to be the more powerful.

Dr. Klein experimented with the two acids in question to ascertain their influence on definite bacteria, whether having pathogenic properties or not. So far as pathogenic bacteria are concerned, the bacilli of anthrax, swine-plague, and tubercle were selected. After detailing his method of action, Dr. Klein explains that in order to pronounce a particular substance a germicide, it is necessary to show that the substance acting on the organisms destroys their life, and hence incapacitates them under all circumstances from producing either a new brood or the disease which before they were capable of starting. With regard to non-specific organisms, Dr. Klein dealt, first, with the small spherical micrococcus derived through blood of healthy rabbits, but he found that both the phenyl-propionic and the phenyl-acetic acids proved powerless to destroy it. The large spherical micrococcus derived from the same blood was next dealt with, the same failure being observed; and a similar result ensued with the bacterium termo and the bacillus subtilis cultivated in pork broth. The bacillus anthracis was next experimented on, this bacillus having been selected, as Dr. Buchanan explains, because there is no acute infective disease of man or animal the etiology and pathology of which is so well understood as that of anthrax, because the characteristic symptoms it produces during life cannot be mistaken, because its causative relation to a microphyte is beyond dispute, and because its contagium has the advantage of being known to exist in two phases. Where this contagium was dealt with in the form of spores, and was exposed for as long as forty-eight hours to a solution of the two acids, having a strength of 1 in 200, no result was produced, the report explaining that the spores thus experimented on still remained capable of communicating the infection of anthrax to guinea-pigs on inoculation. When, however, bacilli free from spores were experimented on, a satisfactory result ensued, the virulence of the infection was completely destroyed, and it was evident that the destruction was final. A solution of phenyl-acetate or of phenyl-propionate only containing 1 in 2000 of the salt sufficed to produce this result after an exposure of from twenty to thirty minutes, and stronger solutions served the same end in much less time. In the case of the swine-fever virus much the same results followed. The experiments were also extended to the tuberculous virus, the human and bovine virus being separately dealt with, but the desired result was not attained; turberculous matter, as Dr. Buchanan puts it, appearing to be in its power of resistance to these particular "disinfectants" comparable with bacillus anthracis in its phase of spore rather than with its filaments or rods. As yet Dr. Klein, who has been aided by Mr. Lingard in this part of his experiments, has not tested the behaviour of tubercle bacilli towards the two acids under consideration. Incidentally, however, an interesting experiment was made with a view of ascertaining how far the process of boiling affected the activity of the virus of tubercle as it exists in tuberculous sputum. The sputum being mixed with 0·6 per cent. solution of common salt was boiled for as long a period as ten minutes; but on inoculation into guinea-pigs it produced the same nodular enlargements of the inguinal glands which follow on the inoculation of the unboiled sputum.

Whilst dealing with the virus of swine-plague a further experiment was made by Dr. Klein, which goes to indicate the value of chlorine as an air disinfectant. In a series of cases he produced swine-plague in a pig, and when the animal was in a state which is known to be capable of conveying the infection to another pig by means of the surrounding air, the air in the stable in which the diseased pig was placed was made pungent with chlorine gas, and a second pig was made to occupy an

adjoining stall, the experiment with the second pig being repeated over and over again. The healthy pigs were, as a rule, exposed for six hours each day during several days, and when the evolution of chlorine was repeated at the end of the first three hours no harm resulted to them; but the failure in one case thus to keep the air in the stable thoroughly pungent with chlorine resulted in the disease being conveyed to one of the hitherto healthy pigs.

These experiments are probably the most precise which have been recorded as to the value of aerial disinfectants, and they are regarded as so far satisfactory that the medical officer to the Board announces that they will be repeated and developed on a larger scale, "in the hope of obtaining some available guides for actual sanitary practice."

Reverting to the experiments which Dr. Klein recorded in last year's report as to the mitigation of poisons by attenuation, it is still evident that the results which were promised by M. Pasteur are not achieved by the adoption of his methods, but it would appear highly probable that a change in the power of an infective organism, anthrax for example, is produced as the result of its passage through different species of animals. Some further information is also supplied in the report as to pathological researches in connexion with tubercle.

Although Dr. Buchanan is unable to announce that any practical conclusion has as yet been arrived at in regard to either of the scientific branches of investigation which are being carried out under his supervision, it is probable that no subjects could be indicated concerning which extended knowledge of a precise sort would be likely to prove of greater value in connexion with the prevention of disease than those which are dealt with in this portion of his report, and it must be remembered that although the process of discovery in such matters is perhaps the more slow because the workers employed so well know the pitfalls that have to be avoided, yet at every stage some valuable information is procured which serves to direct others who are labouring in similar directions. From this point of view alone the report under consideration has a special value.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

A SPECIAL general meeting of the Fellows was held on the 10th instant, presided over by Mr. E. H. Bennett, to consider alterations in the Supplemental Charter and Bye-laws of the College as proposed by the Council. A notice of motion by Dr. Brunker in reference to the election of Council by ballot papers was ruled by the President as unnecessary, having already been adopted by the College. Mr. Mapother moved that Clause 5, as amended by the Council, should be adopted. The clause had reference to the chairman of the day at any meeting having a casting vote in case there should be an equal number of votes recorded. This was seconded by Mr. Gore, but Mr. Hamilton thought it placed in the hands of the chairman a very grave and great responsibility, and might have a prejudicial effect. Mr. Mapother was willing to admit the rule in the case of the chairman of a meeting of Council, which was accepted by Mr. Hamilton and adopted. Clause 7 had reference to Bye-laws hereafter made being approved by his Excellency the Lord Lieutenant instead of by the Secretary of State. Dr. Cameron, Vice-President, who moved its adoption, said it would save expense and trouble. Mr. Corley seconded it, and it was passed. Clause 11: By this clause professors and lecturers are prohibited from being examiners. The Council recommended the propriety of cancelling this prohibition; no examiner to hold office for more than three consecutive years, and not more than two teachers connected with any one school or hospital to be eligible for seats on the Board of Examiners. Proposed by Mr. Wharton, seconded by Mr. Corley, and adopted. Clauses 12 and 13 had reference as to the election of Council by ballot papers, and their adoption was proposed by Dr. Brunker, seconded by Dr. Robinson, and passed. Clause 19 was proposed to be amended by adding that candidates for letters testimonial of the College should satisfy the Council that they were of good moral character. Proposed by Mr. McGusty, seconded by Mr. Wharton, and adopted. Clause 19: Mr. Mapother moved that candidates who possessed other qualifications in medicine and surgery than that of the College should be permitted to be examined for the diploma in midwifery. This was seconded by Mr. Nixon, and passed.

The next business had reference to the admission of women to the diplomas of the College. In considering in committee the changes of Charter proposed by the Education Committee, the Council resolved, "That a new clause be inserted, to provide that all provisions of the Charters, Bye-laws, and ordinances as to education, examination, and granting of diplomas to Fellows or Licentiates shall extend to include women." Dr. Cameron (Vice-President) thought the suggestion of the Council should be adopted, and that it was necessary to pass it if they intended to join the College of Physicians for a conjoint diploma. Although he did not consider women eligible for the surgical part of the profession, yet he thought the College should not prevent them obtaining a surgical qualification, if they so desired. He proposed the adoption of the resolution, which was seconded by Sir Robert Jackson. Mr. Hamilton said he wished to amend the clause by leaving out the term "Fellow." He thought they satisfied the demand of the public by throwing open the College to women. The amendment was seconded by Mr. Joliffe Tufnell. Mr. P. C. Little thought that any Licentiate, according to the Charter, was eligible for the Fellowship. Dr. Kidd supported Mr. Hamilton's amendment, and considered it the duty of the College to admit women, and it was wrong to throw any impediments in their way; on the contrary, they should remove all obstacles. At the same time he thought it a mistake on the part of ladies to join the profession. He believed that it was the intention of Government that women should, as well as men, be entitled to all the advantages of admission to the medical profession. Mr. Wharton agreed with Mr. Little, and asked could the President receive the amendment. The President ruled that the amendment applied to a change in the Charter, and could be received. Mr. Jacob thought it discretionary on the part of Council to refuse admission to the Fellowship; and Mr. Thomson thought it illogical, if women were admitted Licentiates, to refuse them the Fellowship. Mr. Martin considered the Fellowship admitted to the corporate rights of the College, and therefore did not think it advisable, for that reason, to admit women to the higher qualification. Mr. Corley spoke in favour of the proposal to admit women, and thought, sooner or later, they would have to adopt the example of the College of Physicians. On the amendment being put, the President decided the ayes had it, but on a division being demanded it was lost by eighteen to fourteen votes. The original resolution was ultimately adopted by twenty-five to eleven votes.

THE OUTBREAK OF SMALL-POX AT THE THREE COUNTIES ASYLUM.

WE are indebted to Mr. Swain, Medical Superintendent of the Three Counties Asylum at Arlesey, for particulars of the recent serious outbreak of small-pox at that institution. It would appear that the disease suddenly manifested itself almost simultaneously in three different wards. The first case was suspected on December 11th in the person of a patient, a young woman suffering from secondary dementia, who had been resident in the asylum for two years. She gave no warning of her illness, and the first evidence of her condition was the presence of a papular eruption. She was immediately isolated; on the following day six other patients and two nurses showed symptoms of having been attacked, and in five days it was found that forty persons were infected. These were all removed to the detached hospital connected with the asylum as soon as suspected. The attack then seemed to abate, and the cases occurred at intervals and in much fewer numbers till the total reached fifty-six, at which it now remains. By the 17th a large quantity of guaranteed lymph had been procured, and on this and the following three days the entire number of patients and staff (about 1200 persons) were vaccinated. To this fact Mr. Swain attributes the checking of so sudden and so general an onslaught of the disease.

The patients attacked were chiefly amongst the feeble and demented, two being general paralytics and a large proportion epileptics. The disease assumed a malignant form in many cases; and the number of deaths, fourteen, has been consequently high. Amongst these were two

patients aged seventy-one and eighty-six years respectively, one general paralytic, and several unvaccinated. One nurse, who had not been vaccinated as a child, contracted the disease and died. There were five nurses in all attacked. The cases occurred chiefly amongst those sleeping in a large associated dormitory, where patients mostly epileptic and suicidal are kept under continuous observation. There has been only one case on the male side. Those remaining in the hospital are progressing favourably, and it is hoped that the outbreak has been successfully checked.

The source of infection, notwithstanding the closest investigation, remains a mystery; but it may be worth mentioning that one of the local newspapers reports the fact that a person with small-pox eruption actually out on him was refused admission into a London hospital as there was no room, and was allowed to depart and travel down by the Great Northern line to a neighbouring village, where since there have been six cases with two deaths.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6376 births and 4255 deaths were registered during the week ending the 10th inst. The deaths showed an increase of 60 upon the number in the previous week, and were equal to an annual rate of 24·9 per 1000 of the estimated population of these towns in the middle of this year, against 20·2 and 25·0 in the preceding two weeks. During the thirteen weeks ending the 27th ult. the death-rate in these towns averaged 21·4 per 1000, against 23·0 and 21·2 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 19·0 in Bolton, 19·1 in Brighton, 19·6 in Sheffield, and 20·4 in Bradford and in Derby. The rates in the other towns ranged upwards to 30·9 in Manchester, 31·0 in Leicester, 34·8 in Preston, and 36·0 in Cardiff. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 311 and 375 in the previous two weeks, were 372 last week; these included 38 from measles, 51 from scarlet fever, 42 from diphtheria, 37 from "fever" (principally enteric), 36 from small-pox, and 27 from diarrhœa. No death from any of these zymotic diseases was recorded last week in Birkenhead, whereas they caused the highest death-rates in Leicester, Wolverhampton, and Cardiff. The greatest mortality from whooping-cough was recorded in Sheffield and Wolverhampton; from measles in Newcastle-upon-Tyne, Leicester and Cardiff; from scarlet fever in Leeds and Halifax; and from "fever" in Newcastle-upon-Tyne. The 42 deaths from diphtheria in the twenty-eight towns included 26 in London, 4 in Bristol, and 3 in Liverpool. Small-pox caused 48 deaths in London and its outer ring of suburban districts, 1 in Liverpool, and 1 in Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1079 and 1013 on the preceding two Saturdays had further fallen to 1001 at the end of last week; the admissions, however, which had been 244, 161, and 171 in the previous three weeks, rose again to 224 last week. The Highgate Small-pox Hospital contained 87 patients on Saturday last, against 92 at the end of the previous week; 22 cases were admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 416, 370, and 537 in the preceding three weeks, further rose to 609 last week, and exceeded the corrected weekly average by 93. The causes of 113, or 2·7 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, and Leicester, and in six smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Huddersfield, Salford, and Birkenhead.

[1] Omitted from previous lists.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 26·9, 29·6, and 30·7 per 1000 in the preceding three weeks, was 30·5 in the week ending the 10th instant, and was 5·6 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 20·2 and 20·5 in Paisley and Leith, to 34·9 in Perth and 35·5 in Glasgow. The 744 deaths in the eight towns included 30 which were referred to whooping-cough, 26 to measles, 16 to diarrhœal diseases, 12 to scarlet fever, 5 to diphtheria, 5 to "fever," and not one to small-pox; in all, 94 deaths resulted from these principal zymotic diseases, against 110 in each of the preceding two weeks. These 94 deaths were equal to an annual rate of 3·9 per 1000, which exceeded by 1·7 the mean rate from the same diseases in the twenty-eight English towns. The 30 deaths from whooping-cough exceeded the number returned in recent weeks, and included 16 in Glasgow, 5 in Perth, and 3 in Edinburgh. The fatal cases of measles, on the other hand, which had been 34 and 38 in the previous two weeks, declined to 26 last week, of which 19 occurred in Glasgow and 5 in Dundee. The 16 deaths attributed to diarrhœa considerably exceeded the numbers in recent weeks, and were 7 above the number in the corresponding week of last year. Of the 12 deaths from scarlet fever, showing a further decline from the numbers in the preceding two weeks, 8 occurred in Glasgow and 2 in Edinburgh. Four of the 5 deaths from diphtheria were returned in Glasgow, and the 5 from "fever" were fewer than in any recent week. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 174 and 203 in the previous two weeks, were 198 last week, and were 53 above the number returned in the corresponding week of last year. The causes of 92, or more than 12 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 34·1, 26·6, and 38·5 per 1000 in the preceding three weeks, declined again to 31·2 in the week ending the 10th inst. During the thirteen weeks ending the 27th ult. the death-rate in the city averaged 29·4 per 1000, the mean rate during the same period not exceeding 19·8 in London and 19·7 in Edinburgh. The 211 deaths in Dublin last week showed a decline of 48 from the high number in the previous week, and included 19 which were referred to the principal zymotic diseases, against 13 and 24 in the previous two weeks. Of these 19 deaths, 6 resulted from scarlet fever, 5 from "fever" (typhus, enteric, or simple), 3 from measles, 2 from diphtheria, 2 from whooping-cough, 1 from diarrhœa, and not one from small-pox. They were equal to an annual rate of 2·8 per 1000; the rate from these diseases last week being equal to 2·0 in London and 1·9 in Edinburgh. The fatal cases of scarlet fever and of "fever" showed a decline from the numbers returned in the previous week. The deaths from whooping-cough and diphtheria, on the other hand, were more numerous. Six inquest cases and 5 deaths from violence were registered within the city, and 70, or a third of the deaths, were recorded in public institutions. The deaths of elderly persons showed a further

increase upon recent weekly numbers, while those of infants had declined. The causes of 29, or more than 13 per cent., of the deaths registered during the week were not certified.

MORTALITY IN LARGE ENGLISH TOWNS IN 1884.

The average death-rate during the fifty-two weeks ending 27th ult. in the twenty-eight large English towns, including London, dealt with in the Registrar-General's weekly return was equal to 21·5 per 1000 of their population, estimated at 8,762,354 persons in the middle of last year. This rate was slightly lower than the rates recorded in these towns in 1882 and 1883, which were 22·3 and 21·6. In London the rate last year did not exceed 20·3, while it averaged 22·6 in the twenty-seven provincial towns, having an aggregate population somewhat exceeding that of London. The recorded rates in these provincial towns ranged from 17·8 and 18·4 in Brighton and Bristol, to 26·4 and 27·2 in Manchester and Preston. The sex and age proportions of the populations in these towns, however, vary widely, and it is necessary to take account of such variations before using the rates of mortality in the several towns as trustworthy measures of the health of the different communities. The Registrar-General in his last annual summary for 1883 published the factors for correcting the recorded death-rate in each of these towns for differences in the sex and age constitution of their populations. By applying these factors to the mean recorded death-rates in the fifty-two weeks ending December 27th last, corrected death-rates are obtained which are trustworthy for comparative purposes as a measure of the health of the several towns during 1884.

Death-rates in 1884.

Towns.	Death-rate per 1000 living. From all causes. Recorded.	Corrected.	From principal zymotic diseases.
Twenty-eight towns ...	21·5	22·9	3·5
Brighton	17·8	18·3	1·7
Bristol	18·4	19·0	1·8
Derby	18·4	19·1	2·2
Portsmouth	19·3	19·8	3·0
Norwich	21·0	20·1	3·1
Birkenhead	19·4	20·7	2·3
Plymouth	21·1	21·0	2·0
London	20·3	21·5	3·4
Huddersfield	19·6	21·5	1·8
Hull	21·1	21·8	3·6
Bradford	20·1	22·2	2·4
Birmingham	21·4	22·8	3·9
Leicester	22·0	23·0	4·1
Sheffield	22·4	24·1	4·2
Sunderland	23·1	24·1	3·5
Salford	22·2	24·2	4·3
Nottingham	22·9	24·3	3·9
Newcastle	23·0	24·3	3·2
Wolverhampton	23·7	24·4	3·9
Halifax	23·4	25·4	2·4
Leeds	24·2	25·9	4·9
Blackburn	24·0	26·2	4·1
Cardiff	24·2	26·3	4·7
Bolton	24·1	26·4	4·4
Oldham	24·5	27·2	3·5
Liverpool	25·2	27·6	4·5
Manchester	26·4	29·4	3·7
Preston	27·2	29·5	5·2

The figures in the accompanying table are instructive, the towns being arranged in the order of their corrected death-rates from the lowest. It will be observed, however, that the order of the recorded rates differs but slightly from that of the corrected rates, showing that the crude death-rate per 1000 living may be accepted as a fairly approximate test of the health condition of a population, when the means for correction are not readily available. The excess of mortality due to urban aggregation is, however, almost always understated if town death-rates are not corrected for the abnormal age constitution of urban populations. The lowest corrected rates for last year were 18·3 in Brighton, 19·0 in Bristol, 19·1 in Derby, and 19·8 in Portsmouth; whereas five Lancashire towns appear at the bottom of the list: Bolton, 26·4; Oldham, 27·2; Liverpool, 27·6; Manchester, 29·4; and Preston, 29·5. In the last column of the table is given the death-rate in each town from the principal zymotic diseases, which ranged from 1·7 in Brighton and 1·8 in Bristol and Huddersfield, to 4·7 in Cardiff, 4·9 in Leeds, and 5·2 in Preston. Although the zymotic rates do not run in the same order as the corrected rates, there is a general agreement between them, and excessive zymotic fatality accounts for a considerable proportion of the excessive death-rates from all causes. Brighton, indeed, has the lowest corrected death-rate and the lowest zymotic rate, while Preston is absolutely at the bottom of the list, whether judged by its corrected death-rate from all causes or by its death-rate from the principal zymotic death-rates. The excessive mortality in Manchester and Preston, maintained year after year, entails serious responsibilities upon the sanitary authorities of those towns. It is noteworthy that six of the seven Lancashire towns (included in the twenty-eight towns) appear among the seven at the bottom of the list. Salford takes a higher place, standing in the sixteenth place from the top. The health of Salford has markedly improved in recent years, but its death-rate is probably favoured by the fact that its population consists in great measure of the outgrowth of Manchester; in fact, the two municipalities form one city, and should be under one sanitary organisation.

"Audi alteram partem."

THE IMPROVED SANITARY STATE OF FORT WILLIAM.

To the Editor of THE LANCET.

SIR,—The letters of Deputy Surgeons-General Marston and De Renzy on the extinction of cholera epidemics in Fort William, with some remarks on the same subject by Professor Pettenkofer,[1] lead me to believe that I can throw some light on the origin of the improved medical history of the garrison of that fortress, which is rightly regarded by Dr. Marston as instructive, interesting, and deserving of exhaustive investigation.

I was myself quartered in Fort William in 1840, when in temporary medical charge of the 21st Royal North British Fusiliers, to which regiment I was attached when it was in a most sickly state; and I had an opportunity in 1858, a quarter of a century since, of carefully and minutely examining its eminently insanitary condition, as I will now proceed to narrate as briefly as possible.

My friend, Lieut.-Col. (now General Sir Orfeur) Cavenagh, was at that time Town Major of the Fort, and under his skilled and untiring guidance I visited every part of the fortress, and scrutinised carefully every structural and other arrangement connected with it which appeared to have any direct relation to the health of the garrison, and the lamentable amount of preventable sickness which had long prevailed among the troops, native and European. To the Sipahis duty in the fort was at that time almost a terror, as I found when I joined the 47th Native Infantry at Barrackpore, and it was the turn of my regiment to furnish the native guard. Nearly every man told off for the duty feigned sickness to escape it, as they averred on account of its great unhealthiness, a dread I afterwards found to be by no means ill founded.

In May, 1858, Dr. E. Campbell, then garrison surgeon, brought to the notice of the military authorities certain grave defects in the drainage, conservancy, and some other arrangements of the fort, which he believed to exercise a prejudicial influence on the health of the troops, and he suggested measures for their improvement.

The soundness of Dr. Campbell's views, and the accuracy of some of his statements, as well as the feasibility of the remedies he proposed, were questioned by the garrison engineer and town major, while both admitted the great desirability and importance of removing effectually every cause of unhealthiness found to exist in the enceinte of the fortress. They differed from him chiefly as to the right methods of dealing effectually with them. In these circumstances the Government of India appointed a special

[1] THE LANCET, January 3rd, 1885, and December 13th, 1884.

committee to examine and report as speedily as possible upon the question.

The committee consisted of Colonel Paton, Deputy Quartermaster-General of the Army, Staff-Surgeon (now retired Inspector-General) James Anderson, and myself, who then occupied the office of Inspector-General of Prisons. Dr. Anderson was well acquainted with the fort, having had charge of the 2nd European Fusiliers when in the garrison, and I then possessed a less intimate acquaintance with it, as mentioned above. The committee was appointed in July, 1858, and, after much consideration and examination, submitted a report of the results of their inquiry early in September of the same year. The matters specially inquired into were the drainage of the fort, its water-supply, and conservancy arrangements, which were all found to be extremely defective. The objectionable state of all these was detailed, and remedies were suggested for their improvement. The strength of the garrison at that time, including all hands, was 5170 souls.

We recommended that the garrison surgeon and assistant-surgeon should be *ex-officio* the sanitary officers of the fort, and bring all matters affecting its healthiness to the immediate notice of the military authorities. Dr. Campbell had proposed a special sanitary officer, a view in which we were unable to concur, as it was clearly a part, and a very important part, of the duties of the garrison medical staff. Our conclusions included the entire reconstruction of the drains and relevelling of the enceinte of the fort, so as to secure the removal of all impurities at once; the extension of the water-supply of the garrison by the formation of special tanks or reservoirs for the storage of water for drinking and cooking, and by the pumping up and filtration, with the aid of steam-power, of a sufficiency of river water for all cleansing and conservancy purposes; the provision of a plunge-bath, and the reconstruction of the latrines and lavatories; the reduction of the vegetation in the fort; the more free use of charcoal as a deodorant and disinfectant; an entire change in the urinals, and the daily removal of all excrementitious matters; improvements in the garrison cells; the ordure of the fort, which was not carried off by the *Cunette*, to be transported to a distance down the river in a properly constructed covered filth boat; and the *Cunette* being strictly confined to its proper use in time of peace, and more thoroughly cleansed and scoured than it then was.

The cordial thanks of the Government of India were conveyed to the committee for the thorough manner in which the duty was performed and for the clear and able manner in which the results of their investigation were embodied in the report.[2] Immediate orders were issued to the Public Works Department to carry out all the recommendations that were practicable with the least possible delay, and thus commenced measures which have not since been relaxed, to secure the healthiness of Fort William. The table printed by Dr. Marston shows how quickly the good effects of those measures were experienced as respects cholera, and that it preceded by several years the introduction of the filtered water of the Calcutta Municipality. I entirely concur with that officer in considering that the improvement of the health of the troops in Fort William was due to sanitary improvement all round, and not to any single cause, however important.

I may possibly take another opportunity of stating my views on the cholera portion of the question, for I recently had an opportunity of again seeing that disease in Paris during the present epidemic, when I found not the smallest difference between its ordinary course and characteristics as I witnessed them half a century ago in the same city, and as I found them a few weeks since.

The pathology of cholera is still a sealed book, and until the mystery of its origin is revealed we must, I am afraid, be content to rely on prophylactic measures to prevent its introduction or extension. These were as well understood thirty years ago as they are now, as can be proved from published records, should it be necessary. Continental nations are now realising the inefficacy, and even danger, of quarantine regulations as they are, and can only be carried out. The circulars recently issued on the subject at home and abroad have added nothing whatever to our knowledge of the matter, and are not likely to do so in existing circumstances.

I am, Sir, yours faithfully,

F. J. MOUAT, M.D.

FRACTURES OF THE SKULL, FOLLOWED BY COLLECTIONS OF CEREBRO-SPINAL FLUID BENEATH THE SCALP.

To the Editor of THE LANCET.

SIR,—Since my friend Mr. Godlee has directed attention to my papers on this rare condition, and has brought before the Pathological Society two cases bearing upon the subject, I should be glad to be allowed to make a few further comments on the circumstances with which this phenomenon is associated. My four short papers have been published in the Guy's Hospital Reports for 1876, 1878, 1881, and 1884, and have hitherto (as Mr. Godlee suggested) escaped the notice of the profession in this country, though the first case attracted the attention of Professor Verneuil in Paris, who published some comments upon it. In these papers I gradually arrived at more decided opinions, and in my later papers I ventured on two definite conclusions—viz.: 1. That simple fractures of the skull, followed by tumours of cerebro-spinal fluid beneath the scalp, occur only in children. 2. That when cerebro-spinal fluid escapes in quantity from the vertex (whether the fracture be simple or compound) the ventricle of the brain has been laid open. The first of these conclusions is borne out by the record of all the published cases, and I reasoned out its truth for the future in the following way: The skulls of children are flexible, and when the bones are fractured the edges of the fracture may be driven far into the brain without damage of the scalp. In adults, on the other hand, owing to the rigidity of the bones, one fractured edge will almost certainly cut through the scalp before the other can penetrate far into the brain.

The second conclusion, though contrary to the ordinary teaching, which supposes that in the majority of cases cerebro-spinal fluid escapes from the subarachnoid space, is nevertheless supported by all post-mortem evidence; and I would here suggest that in suspected cases, to prevent error after death, the brain and its covering ought to be hardened for some months in spirit (as was done in both my cases) before being examined. Again, compound fractures of the skull, with injury to the brain and without escape of cerebro-spinal fluid, are common, the reason of this being that the subarachnoid space on being injured rapidly throws out a greenish solid lymph, which glues up its cavity.

I would submit that neither of Mr. Godlee's interesting cases was a true case of cephal-hydrocele, and that they ought not to be included in any table of such cases. In neither was the fluid withdrawn, the clear, faintly albuminous, watery, cerebro-spinal fluid, though it would appear from the post-mortem examination in the first case that the conditions were present which might eventually have led to such a tumour being formed after the blood and inflammatory products had been absorbed.

The pulsation of a tumour beneath the scalp will occur whenever there is a direct and free communication through the bone between the tumour on the outside and the contents of the skull, whether that tumour be soft, solid, cerebro-spinal fluid, serum, or blood. In this respect a comparison may be drawn between the pulsation occurring with a hole in the calvaria and the impulse on coughing communicated to all tumours, fluid or gaseous, which have a free communication with the abdominal cavity, the impulse from within being felt externally where the wall is deficient. The diagnosis of cerebro-spinal fluid tumour must rest on other grounds than pulsation and increase in size when the child cries. I pointed out that there was a peculiar thinness (for lack of a better word) in the feeling of fluctuation, and a tendency to displacement, which allows the gap in the bone to be distinctly felt. Moreover, the tumour may be translucent, and there is an absence of fever such as is present when the tumour contains pus. As regards treatment, I insisted in my first paper, in 1876, upon the wisdom of leaving these cases as much as possible to nature. Aspiration cannot assist the cure, and appears to add seriously to the danger. It is, therefore, only justifiable as a means of diagnosis, and then is best performed with the needle of a hypodermic syringe.

Now that attention is being drawn to this class of head injuries, it is to be hoped that observers will carefully distinguish between the serum of blood-clot and the watery, barely albuminous, cerebro-spinal fluid.—Yours truly,

R. CLEMENT LUCAS, B.S., F.R.C.S.

Finsbury-square, Jan. 10th, 1885.

DARENTH SMALL-POX CAMPS.

To the Editor of THE LANCET.

SIR,—In consequence of the discussion now going on in the public journals, both general and professional, regarding the Darenth Small-pox Camps, and the conflicting statements therein contained, I determined to visit them myself, alike in the interests of the metropolitan ratepayers as in the cause of truth and humanity, in order to ascertain by a complete and careful investigation the present real state of things there. I may premise that my visit was totally unexpected, and that not a single member of the Metropolitan Asylums Board was personally known to me. Having during a continuous period of twenty years in the Indian Medical Service had considerable practical experience of camp management, both military and civil, as field hospitals, and camps for epidemics of cholera and gaol fevers in particular, and having been during the last four years of my sojourn there superintendent of the Rawalpindi gaol—one of the largest, and having an average of over 1000 prisoners daily,—I thought I might venture to form an approximately accurate opinion upon the subject.

I arrived at the camps—there are two, one for males and juveniles over ten years of age, the other for females and children, and some three hundred yards apart—at noon, and spent about four hours there, designedly timing my visit so as to be present during the midday meal. I examined and tasted the meat (roast beef), potatoes, pudding (baked currant), the broth and beef-tea, the bread-and-butter, and also the beer, and I found them all, both in quantity and quality, good and well cooked; each patient had also some greens, and those who did not wish for beer were allowed milk-and-water, lemonade, or ginger-beer. The quantity of meat I considered superabundant; there was no fixed quantity, each being allowed to take as much of everything as desired; and I saw with much regret large quantities of beef and mutton, the remains of joints, cast into a tub to be eventually cremated, being informed by the superintendent, Dr. Waylen, and the steward, Mr. Harper, who with a solicitor, specially, and equally unexpectedly, deputed by the Asylums Board to examine into the complaints which have lately appeared in print, accompanied me throughout my searching inspection, that there was no other way of disposing of it.

I afterwards visited the sleeping tents, examined the bedding, the pillows, mattresses, &c., which are filled with horsehair, as well as the personal clothing of many of the inmates, and found them all clean, suitable, abundant, and of superior quality; indeed, in this latter respect, in my opinion, extravagantly so. I also visited the kitchens, the general stores, laundry, bath-room, the disinfecting and engine rooms, as well as examined the sanitary, and especially the conservancy arrangements—the dry-earth system is universal,—the drainage, and the water-supply, and found them all satisfactory. The infirmaries—three, one each for the males, females, and children—I particularly inspected; they are substantial wooden structures, and in cleanliness, order, lighting, and temperature, all that can be expected. I may here state that all the tents and wooden sheds are warmed by means of steam-pipes, and that a suitable temperature, superintended by special attendants night and day, is regularly maintained. During my visit a batch of twenty women and children had just arrived from the ships near Dartford; they were conveyed in a three-horse omnibus, and, although they had travelled during a severe snowstorm, they arrived in a comfortable condition, and their clothing was in every way suitable. All the patients throughout the camps appeared happy and comfortable. I spoke to many of them, of all ages and of both sexes, and they all expressed themselves satisfied; indeed, although in all the places visited the question was loudly asked, there were no complaints; but on our leaving the mess-room of the male patients we were dismissed with loud, lusty, and repeated cheers, which were audible at some distance outside after we left.

In short, the condition of all the patients seemed in all respects highly creditable to the local authorities; and I noticed particularly the respectable appearance and gentle demeanour of the subordinate establishment, especially of the female nurses. The patients are provided with books, games, and gymnastic apparatus, and there are entertainments—such as singing, recitations, &c.—every evening in the assembly-rooms. Toys and suitable picture-books are also provided for the children; and the scale of diet throughout seems to be a liberal one. The total number of patients was 658. The number of sleeping tents was thirty-five; all of them very large and lofty, having double flys, and standing upon raised brick pillars, about three feet high. They are provided with wooden flooring, and the superintendent has adopted, of his own design, and for all of them, glazed doors, giving them the cheerful appearance and lightness of an ordinary dwelling. The estate on which the camps are pitched consists of about 300 acres; the site is ample, sloping, well sheltered by the adjoining Darenth wood, and overlooks some of the most beautiful scenery in the country. It is about 400 yards from the main road, and from the three or four residences about it; the inhabitants of which are thus completely insured against the possibility of being contagiously affected. The establishment appears ample and efficient. The superintendent seems entirely devoted to his somewhat disagreeable duties, and he is assisted by two fully qualified assistants.

There appears to me to be no grounds whatever for any anxiety regarding the welfare of these poor and unfortunate patients, whose condition has naturally excited the sympathetic solicitude of the general public, and the managers of the asylums board deserve the highest praise and the best thanks of the community for their efforts in so rapidly organising this large and novel institution.

I am, Sir, yours truly,

JOHN INCE, M.D.,
H.M.'s Indian Medical Service, Retired List.

Jan. 12th, 1885.

TUBERCLE BACILLI AT THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

To the Editor of THE LANCET.

SIR,—As I was prevented by the rules of debate from speaking again in the discussion on tubercle bacilli at the Medical and Chirurgical Society on Tuesday evening last, perhaps you will kindly allow me a few lines of your space to say that I heard nothing from Mr. Watson Cheyne which directly met my statements and inquiries made at the previous meeting. We are still left in doubt as much as ever whether Dr. Koch strictly adheres to the fractional principle in his cultivations. In one passage of his report to the Association for the Advancement of Medicine by Research, Mr. Cheyne would have us believe that the fractional principle was adhered to by Dr. Koch throughout a long succession of cultivations, although Dr. Koch himself withholds the detailed information on that point, not only in his first paper, but equally in his final reports of eighteen months' later date. In another passage Mr. Cheyne implies that the whole of the first cultivation was transferred to the second test-tube, "and so on." In his remarks on Tuesday evening, he seemed to treat the quantity of scales or crusts carried forward as a matter of indifference, and even of uncertainty. But everyone knows that the very principle of the pure cultivation of fungi which was introduced by Brefeld (and which I saw applied to disease-producing fungi by Dr. Grawitz at Berlin eight years ago is to make each successive crop of organisms grow from the smallest possible fraction of the former crop.

It is needless for me to meet Mr. Cheyne's round assertion that I am from first to last in error. My printed statements as to matters of fact are all authenticated by references, and they are not to be overthrown by a display of virtuous indignation. As to my interposition in this business, I do no more than exercise the right and duty of every member of the profession to hold and express an intelligent opinion on a disease which confronts us every day.

I am, Sir, your obedient servant,

C. CREIGHTON, M.D.

New Cavendish-street, W., Jan. 14th, 1885.

COCAINE AS A LOCAL ANÆSTHETIC.

To the Editor of THE LANCET.

SIR,—Evidence of the value of cocaine is so rapidly accumulating that additional testimony seems scarcely required. I should, however, be glad to add a few lines to my letter which you published on Nov. 22nd. I have continued to use it in varying quantities for many purposes, and seldom without satisfactory results. Ophthal-

surgeons have found a weak solution sufficient, and it is desirable to economise its use. In laryngeal cases weak solutions often suffice, but, as I have said, stronger ones may be required. I have had to employ 10, and sometimes 20 per cent.; but have often avoided this by using repeated applications of 2, 4, or 5. Much depends on the depth to which it is necessary to induce, and the time it is required to maintain, anæsthesia. I have succeeded six times in growths of the larynx without exceeding 5 per cent. When the attachment is firm and deep this will not be enough. In the nose 5, 10, 15, or 20 per cent. may be required, according to the extent and depth of anæsthesia necessary. Superficial anæsthesia may be produced in this and other mucous membranes by 2 to 5 per cent. Tactile anæsthesia may be tolerably complete when sensibility to thermal and other impressions is incomplete. In three cases of excessive hyperæsthesia I have completely removed the condition with 2 and 4 per cent. In seven or eight cases of excessive pain in late laryngeal phthisis it has been quite arrested by cocaine. In extreme dysphagia in the same disease some patients have been enabled to take food after sparing but careful use of the anæsthetic. In several of these cases a weak solution of 1 or 2 per cent. has answered. The remedy may be used as a spray instead of painting. This a weak spray for a very short time renders the throat or nose anæsthetic.

There is another effect which none of your correspondents notice. The cocaine produces pallor, sometimes quite extreme, of the membrane to which it is applied. This it would do in health, and in the same way it often causes the immediate disappearance of hyperæmia, an effect the importance of which is obvious. Considering that there may be an arrest of our supply, it would be well if those who are using the alkaloid internally would content themselves for a time with a fluid extract of the cuca leaves, which can be easily obtained. For fear of encroaching too much on your space, I will only add to-day that I had anticipated Dr. A. H. Bennett's suggestion, and have made a number of experiments with other alkaloids, the results of which I shall be happy to furnish if you can find room for them in THE LANCET. I am, Sir, yours truly,

Bean-street, Park-lane, Dec. 6th, 1884. PROSSER JAMES.

To the Editor of THE LANCET.

SIR,—A lady suffering from two small recto-vaginal fistulæ, who had been three times operated upon by a distinguished London surgeon with only a partial amount of success, came under my care a few days ago. The fistulæ now being small I determined to "raw" the edges by means of the actual cautery, using that of Paquelin for the purpose. Before applying it I painted the vaginal surfaces thoroughly well with a 4 per cent. solution of the hydrochlorate of cocaine. Partial insensibility ensued in about two minutes, and the patient bore the operation very well, remarking that she "felt the burning, although she did not feel pain." I was pleased and yet disappointed; pleased that she "did not feel the pain," but disappointed after the glowing accounts I had read with regard to cocaine that she should "feel the burning." Were I using it again I would employ a stronger solution, say 10 per cent., as subcutaneous injection in my case, owing to the thinness of the tissues, would hardly have been practicable.

I am, Sir, yours faithfully,

J. RUDD LEESON, M.D. Edin.,
Late Demonstrator of Anatomy, St. Thomas's Hospital.

Wimbledon, Jan. 10th, 1885.

"AGORAPHOBIA."

To the Editor of THE LANCET.

SIR,—Having seen in your last impression a request from a surgeon to give an account of a case of agoraphobia treated satisfactorily, I venture to write to your valuable journal and offer suggestions founded upon a case for some years under my care, which has ended in complete recovery, whether *post hoc* or *propter hoc* it is not for me to say.

The patient was a robust man, in the prime of life, between thirty and forty, fond of exercise, above the average intellectual development, but much subject to the "blues." I have always maintained it is not a *disease*) to which has been given the pedantic title of "agoraphobia." I have no hesitation in affirming that this symptom is usually due to sexual and alcoholic excess. We all know that some men can indulge to a much greater extent in the two excesses above-named without any serious consequences than can others. And it is the imitation of these Sileni and Priapi by their weaker brethren which constitutes the chief cause of agoraphobia.

In my experience the exhibition of drugs is of little avail in such cases. The fault is not on the side of morbid excess, but of morbid imitation; and if you can once get the patient to recognise this fact, the cure is, as a rule, in his own hands. Tonics stimulate the already excessive desire; whereas sedatives, such as bromide of potassium, debilitate the patient to such a degree as to prevent his carrying out his daily avocations. The agoraphobic patient should keep a strict account of his expenditure to the heathen gods (Bacchus or Venus), and should use his best endeavours to lessen it. He should also endeavour to keep an account of the number of hours he walks in the day, and should increase them as his strength improves. He should also note the time he goes to bed and the time he rises in the morning, especially remarking if he should be awake in the night, and for how long.

This is not the place to enter into a discussion on insomnia, although this, too, is undoubtedly a minor cause of agoraphobia. As a rule, the simplest remedies for this disease are the best. My favourite prescription is an hour's brisk walk in the open air before going to bed, followed up by a hot glass of wine and water, not forgetting the nutmeg.

I may, I hope, be excused if I add a few empirical hints gleaned from my patients in these cases. The patient must be spirited and courageous; he must force himself into the street to take walking exercise. The pace should be slow for the first quarter of an hour, and then worked up by slowly increasing degrees to the usual speed. Should the symptom be very aggravated, the patient should only (in London) walk in the open streets, where he can obtain a cab should he require one. Should he be obliged to traverse any short distance, across an open space, and should he then feel that horrible sensation (described by Legrand du Saulle) of the heart being squeezed as in a vice, a few sharp blows with his fist on the epigastrium will restore the action of the organ to regularity, and often bridge over the abyss till he can reach a place of security. Agoraphobia depends much on association; therefore let the patient avoid all places in which experience has shown him that the sensation is apt to arise.

Claustrophobia generally accompanies agoraphobia. This is not the fear of *open* spaces, but the fear of *shut* spaces. Most of the cases under my care have experienced this sensation when at stool. This I attribute to two causes: one physical, which is the debilitating effect of passing the fæces; the other moral, from the fear that if the patient should faint he might fall against some object and injure himself. A patient liable to faint at stool (and this is very common) should leave the door of the closet unbolted, and have a servant outside ready to respond to his call should he feel unwell. Far be it from me to encourage the practice of secret drinking; but I have known one agoraphobic patient much improved by carrying a flask of wine in his pocket, which he could take on an emergency, and in extreme cases even brandy is allowable. A walk with a companion is a most valuable remedy in this disagreeable state of things; as thereby the heart's action is rendered more regular and more powerful, and the fact that there is some one at hand to assist should occasion arise gives the patient a confidence he can never feel when alone.

The treatment of agoraphobia may be thus summed up. 1. Diminish sexual intercourse. 2. Diminish alcoholic stimulants. 3. Increase exercise. 4. Take enough, but not too much, sleep. Your obedient servant,

HENRY SUTHERLAND.

Richmond-terrace, Whitehall, S.W., Jan. 1885.

TREATMENT OF INTESTINAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—If you will allow me a final word in reply to Mr. Steele's letter in your last number, I would merely observe that I consider it amply confirmatory of my original statement, that rest, opium, and starvation had for many years been the recognised treatment in cases of intestinal obstruction. He observes that I "still look upon Mr. Thomas as merely one of many authors who have laid down the so-

called rest, opium, and starvation treatment." That is precisely my view of the matter, while at the same time giving Mr. Thomas every credit for pointing out certain improvements in diet, and for protesting against mechanical remedies when ignorantly and excessively employed. Mr. Thomas says that "between Sydenham and himself a void exists." This is not unlikely, but it fails to convince me that they are the only two persons who have ever known anything about intestinal obstruction. Mr. Steele describes himself as a young practitioner. With increase of years and experience I feel sure that he will discover that to rigidly apply one uniform and restricted method of treatment (to the exclusion of all others) to a disease under which are classed pathological conditions as widely asunder as the poles is neither logical nor in accordance with the principles which govern medical science in other instances.

I am, Sir, your obedient servant,

Liverpool, Jan. 13th, 1885. W. MITCHELL BANKS.

TREATMENT OF FUNCTIONAL AMENORRHŒA.

To the Editor of THE LANCET.

SIR,—Will you allow me to draw the attention of the profession to a remedy for functional amenorrhœa which has been very successful in my hands. It consists in the persevering use of an infusion of the bog- or buck-bean *(Menyanthes trifoliata)*, taken hot every morning half an hour before breakfast, for some weeks if necessary. The rough mode of making this infusion is by half filling a tumbler with the dried plant, and pouring upon it five or six ounces of boiling water over night. This makes one dose, or in some cases two. In order to avoid the inconvenience of this process, Mr. Martindale has kindly made a liquid extract of the drug, the dose of which would be a tablespoonful in half a tumbler of hot water, I am induced to send you this letter in the hope that others will try this remedy and report upon it.

I am Sir, yours faithfully,

Harley-street, W., Jan. 14th, 1885. JULIUS POLLOCK.

THE M.D. EXAMINATION AT THE LONDON UNIVERSITY.

To the Editor of THE LANCET.

SIR,—The published results of the recent M.D. examination of the University of London have occasioned much comment in professional circles, and at the present juncture such comment may not be without influence on the side of those who are agitating for a teaching university in London, unless, as we are informed is likely to be the case, a special committee of the Senate be appointed to inquire into the circumstances.

The examiners in logic and psychology alone rejected 51·7 per cent. of the candidates, including those who presented themselves in both medicine and logic together, and those who entered for the latter subject only. Seventeen candidates entered for the whole examination: of this number eleven passed; six, although passing "a highly creditable examination in medicine," were rejected in logic; and three were rejected in medicine. Now, the most apparent absurdity of this result is the fact that examiners in logic and psychology should be the means of compelling these six legally qualified medical men, who pass "a highly creditable examination in medicine at the M.D.," to be re-examined, not only in their own subject, *but also in medicine*. This fact must have been painfully apparent to the medical examiners when assembled in conclave to decide the results.

Dr. Inflammation: "Candidate A.B. displays a highly creditable knowledge of medicine." Professor Abstract: "Indeed! He has failed to reach the necessary standard in logic and psychology, and it will be necessary for him to be re-examined *in medicine again also*." Why should this be? The examiners in medicine have no power to compel a candidate to appear again in logic, &c., if he passes in logic and failed in medicine.

Might I be allowed to appeal to your readers to explain away by some obscure (or simple if possible) "logical" method the absurdity of these facts.

I remain, yours faithfully,

December, 1884. MEDICUS.

LIVERPOOL.

(From our own Correspondent.)

DEATHS IN LIVERPOOL FROM ZYMOTIC DISEASES IN 1884.

At the last meeting of the Health Committee some interesting statistics, compiled by Dr. J. Stopford Taylor, the medical officer of health, respecting the death-rate during the past year, were read. The deaths from zymotic causes amounted to 2973, of which the following details are given:—

Disease.	Deaths during 1884.	Average for previous ten years.
Small-pox	106	82
Measles	611	441
Scarlatina	197	620
Whooping-cough ...	546	466
Diarrhœa	841	704
Diphtheria	80	53
Fever	205	402

The deaths from fever and diarrhœa were much lower than had ever been known before, a circumstance which may be fairly attributed to the many sanitary improvements which have been lately effected in the city.

HOSPITAL SUNDAY.

Sunday, the 11th inst., being the second Sunday in the year, was observed as Hospital Sunday in Liverpool, collections being made in all the churches, chapels, and other places of worship in the city and suburbs. Unfortunately the weather was most unfavourable, being wet and very boisterous during the whole of the morning; hence a falling off in the amount of the collections has been observed; a circumstance which is much to be regretted, as all the local hospitals and dispensaries are greatly in need of increased support. The total amount advised to the treasurer up till the 14th inst. amounted to £3299.

CONCERTS AT THE ROYAL INFIRMARY.

At the Royal Infirmary a concert was given on the 3rd inst. in one of the wards, which was beautifully decorated for the occasion. The performers were members of the resident medical and nursing staff, aided by friends; among the audience were members of the committee and of the honorary medical staff, with their wives, families, nurses and patients. An excellent programme was gone through, the various songs being extremely well rendered. The audience showed their appreciation by frequent applause, in several cases an encore being demanded, and a most enjoyable evening was spent by the visitors.

DANGERS OF STONE-THROWING.

An inquest was held last week on the body of a boy aged eleven by the borough coroner. It appeared from the evidence that on New Year's Day the deceased was running away from a lad who had used threatening language to him, when he was struck on the back of the head by a stone, which his assailant was seen by a witness to throw at him. The deceased expired on Saturday night from concussion of the brain, and a verdict of manslaughter was returned against the boy who threw the stone, who was only fourteen years of age, and admitted his guilt after being duly cautioned. This dangerous practice prevails to a very considerable extent in Liverpool.

MANCHESTER.

(From our own Correspondent.)

CHEAP DINNERS FOR SCHOOL CHILDREN.

ONE, and by no means the least, of the results followin the agitation on over-pressure in our elementary schoo has been the prominence given to the fact that many of th children attending these are sent in a half-starved conditio often, indeed, commencing their day's work on an almo empty stomach, and as a remedy for which cheap dinne for those who cannot obtain the necessary food at hon have been established. This experiment, commenced London, has been also put upon trial here, chiefly throug the instrumentality of Mr. Alexander Forrest, whose wor

are situate in one of the poorest and most densely populated districts of the city, Holt Town, and who has become very intimately acquainted with the poverty so prevalent around. He with the assistance of some friends has made arrangements whereby during the past two months nearly 200 dinners have been supplied daily. A charge of one penny has been made where possible, but in 15 per cent. of the dinners it has been found, after careful inquiry, that even this small sum was not able to be paid, and free tickets have therefore been given to these. The cost of the dinners has, exclusive of labour, been a trifle over a penny per head, so that some help is required from charitable friends if they are to be continued through the winter. In the discharge of this truly charitable work, the difficulty which meets the philanthropist is the danger of pauperising the parent whilst endeavouring to prevent the starvation of the child.

CHRISTMAS AT THE HOSPITALS.

Christmas and the New Year were celebrated in some of our hospitals. At the Ancoats and Ardwick Hospital a Christmas-tree and some theatricals were arranged for the patients, and were attended by a goodly number of friends of the institution. This hospital has of late been doing much good work. For some years its wards were almost empty; but, thanks to the exertions of a few energetic friends, amongst the foremost being the honorary secretary, Mr. A. Forrest, above-mentioned, two of the largest wards are now fully equipped and filled with patients. At the Eye Hospital, the Children's Hospital (Pendlebury), the Monsall Fever Hospital, and the Infirmary at Hope, some seasonable festivities were provided for the inmates.

HOSPITAL EXTENSION.

At the last meeting of the board of management of the Royal Infirmary a scheme was brought forward and approved for considerable alteration and extension of the Monsall Fever Hospital belonging to that charity. For some years past arrangements have been in force between the infirmary and the corporation of Manchester for the reception at the Monsall Hospital of cases of infectious disease requiring isolation in hospital, the corporation not possessing, like the adjacent borough of Salford, a hospital of their own. The estimated cost of the proposed extension exceeds £20,000, and this the infirmary ask the corporation to find if they desire to continue to use the Monsall Hospital, pointing out that it is no part of the duty of that charity to provide accommodation for the infectious diseases of the city and neighbourhood, and that they cannot be expected to expend this large sum out of the funds of a charitable institution to relieve the health committee of what is essentially part of their duty as the legal sanitary authority of this large population. Unfortunately, at the present time there is a dispute pending between the corporation and the infirmary as to the length of time cases are retained in hospital, the former asserting that they are kept longer than is necessary, thus greatly increasing the cost of isolation, and when the last accounts were sent in by the infirmary board they deducted more than £500 from the bill on these grounds. This the infirmary have firmly resisted, and have notified the health committee that unless the charges are paid in full their patients will no longer be received; and for the present there the matter remains.

At the annual meeting of the Ear Institution it was reported that, owing to the increase of patients, it had become necessary to remove to more commodious premises, and an appeal was made for more subscriptions to meet the increased expenditure connected therewith. It had been found necessary to appoint, for the first time, a house-surgeon. The Lock Hospital, also, is contemplating extending its work by the addition of a special department for diseases of the eye. The committee of this hospital urgently appeal for more help from the public if the work is to be carried on, even to the extent hitherto done.

WATER-SUPPLY.

At the last meeting of the city council an important step was taken in reference to the water-supply of Manchester. The late dry autumn placed us uncomfortably near to a water famine, and it was resolved, on the recommendation of the waterworks committee, that the scheme for bringing water from the Lake district in Cumberland, which has been in abeyance, should at once be actively proceeded with.

EDUCATION AND HEALTH.

On the 9th inst. a largely attended meeting was held in the town hall, for the further consideration of the proposed conference to be held here on education and health. Mr. Oakley (H.M. Inspector of Schools), chairman of the executive committee, stated that Lord Aberdare had consented to become president, and much support was promised to and interest manifested in the proposed meeting, and it was resolved that the necessary steps be at once taken to complete the arrangements for holding the same. From the names of those who have given their approval and promise of help, and from the subjects proposed to be brought forward for consideration and discussion, it bids fair to be a conference of a very useful and interesting character.

The graduates of Aberdeen were somewhat disappointed at their annual dinner recently held at the Grand Hotel by the inability of Sir Andrew Clark to preside thereat, as had been arranged. In his absence the chair was occupied by Dr. Ross, a very enjoyable and convivial evening being spent.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE INFIRMARY.

A SPECIAL court of governors is called at the infirmary for the 23rd proximo, to consider the resolution passed on the 23rd of December last, and which runs as follows:—"That this committee recommends the design of Messrs. Lamb and Armstrong as the best means of adding to the infirmary on its present site; but the medical board, having submitted to this committee the opinion of the staff that the hospital, instead of being added to, shall be removed to another locality, resolved that the whole matter be again referred to the body of the governors, and that for this purpose a general meeting be called this day month." So that we are to have the whole question of enlargement or removal to a new site considered on its merits, full weight, I trust, being given to the recommendation of the medical staff. At a recent meeting of the Newcastle Trades' Council the subject of having a working man as a representative on the infirmary committee was discussed, and upon the whole in a very fair and reasonable spirit. It was stated that there were many questions that came before the infirmary committee with regard to letters of admission, patients' conduct, and nurses' behaviour, that could be adjudicated upon by a working man better than by those who were not in constant communication with those who mostly used the infirmary, and that the experience of the relief committee showed that the working man representatives had been the means of solving many cases of sham distress. Further, it was stated that it was well known that the infirmary was greatly imposed upon by persons who were able to pay for medical aid. One speaker said he knew of families in good circumstances who, whenever the slightest thing ailed them, said, "Go to the infirmary." These people were not in a friendly society, but altogether relied upon the infirmary for their medical requirements. It was pointed out at the meeting that anyone could become a life governor by paying a sum of money, but not a small one for a working man. It was thought that a bye-law might be passed by the infirmary authorities whereby, considering the very important sum of money now contributed by the working classes to the Hospital Sunday Fund, a means might be found for a representative working man being on the house committee.

CURIOUS DISCOVERY OF SKELETONS AT TYNEMOUTH.

The men employed in the excavation for the new park at Tynemouth have come across a quantity of human remains. The whole of the skeletons, numbering, as far as they can be put together, twelve or fourteen, were stated to be above the average height of the present generation; one in particular was stated as measuring 8 ft. 3 in., the skull being also, according to account, of extraordinary thickness; but a later and more careful measurement of the bones went to show, as might have been expected, that the height would be about the average of men of the present day, 6 ft. or so being about the maximum. Not one of the separate pits in which they have been found is more than 4 ft. in depth, the majority of them being from 18 to 20 inches from the surface. They are supposed to have been interred during the Cromwellian era, but this point is not yet decided.

FROST-BITTEN SEAMEN.

The steamer *Rydal Water*, of Liverpool, arrived in the Tyne last week with two seamen very severely frost-bitten while on the passage from New York, which port they left on Dec. 18th last. They say that on the day the vessel left she was covered with ice, and that the spray from the sea no sooner fell upon the crew than it was frozen. The sea swept over the vessel with great force, one wave broke the bridge, and the ship was hove to for three days during the passage, which lasted twenty days. Both men are severely injured in their feet and hands, and have been admitted into the borough hospital, North Shields.

POISONING BY FLUORIC ACID.

An inquest was held last week on the body of a young servant girl who had been living at Tudhoe Grange, near Durham. It seems that on Sunday evening she drank a quantity of fluoric acid, which was used by her master for staining glass. Soon after she took the poison she told the children to tell their mother. Dr. O'Hanlon was soon in attendance, using the stomach-pump and all other means, but his efforts were unavailing, and she died in great agony in three hours and a half after taking the acid. The jury, in giving their verdict, expressed the opinion that such a deadly poison should have been kept under lock and key. It appears to have been left in a cupboard.

THE CARRIAGE TAX.

An important meeting was held here last week on the subject of the carriage tax, the speakers showing its pressure on the medical profession, the trade, and the general community.

Newcastle-on-Tyne, January 14th.

SCOTLAND.

(From our own Correspondent.)

SCOTCH UNIVERSITY STATISTICS.

THESE statistics have some interest in view of the agitation at present going on in London for the establishment of a teaching university there. The matriculation returns for Edinburgh show these results:—The aggregate number of students matriculated during the year being 3401, as against 3396 on the register of the previous year. These were divided between the different faculties as follows:—Faculty of Arts, 1064; Divinity, 113; Law, 500; and Medicine, 1724; the percentage composition being: in Faculty of Arts, 31·2 per cent.; Divinity, 3·2; Law, 14·7; and Medicine, 50·67 per cent. The entries in the register show that of the 1724 students in the latter faculty, 689, or 39·4 per cent. were from Scotland; 605, *or 35·1 per cent., from England;* 44, or 2·6 per cent., from Ireland; 104, or 6·3 per cent., from India; 247, or 14·3 per cent., from the different British colonies; and 34, or 1·9 per cent., from foreign countries. The following is an analysis of the respective ages of students attending the university:—Under sixteen there are 14 students, or equal to 0·41 per cent.; between sixteen and twenty-one, 1573, or 45·7 per cent.; between twenty-one and twenty-six, 1401, or 41·2 per cent.; between twenty-six and thirty-one, 317, or 9·3 per cent.; between thirty-one and thirty-six, 64, or 1·9 per cent.; and between thirty-six and forty and above forty, 16 in each, or equal to 0·47 per cent. The register of members of the General Council for the past year has just been completed, and shows an increase of 237, the number enrolled being 5158, as against 4921 on the last register. In Glasgow there is a slight, but very slight, falling off in the number of matriculated students, the number being 2091, as against 2115 last year. In the faculty of Medicine, however, there is a slight increase, the figures being 557, as against 536 last year.

HEALTH OF GLASGOW IN 1884.

Dr. Russell reports that during 1884 there were 13,929 deaths registered, a rate of 27 per 1000, being 1 per 1000 below the rate of 1883, 1 above the average of the five years immediately preceding, exactly the same as the average of the ten years 1874-83, and 4 per 1000 below the average of the ten years 1864-73. Dr. Russell remarks that, high as the death-rate of 27 is, if we examine the records of the Registrar-General for 1855, when his office was instituted, we shall find that from that date to 1879 the death-rate of Glasgow never fell so low in any one year; and that only in four years of the 29 during which we have had a Registration Act in operation, has it been lower than 27. In appreciating our present position it is always necessary to remember what our death-rates have invariably been until within the last few years. In these comparisons I have adhered wholly to the Registrar-General's rates, which have, since the census, been based on a population below the reality. According to my estimate of the population, the death-rate last year was 25¼. During the past fortnight the death-rate in Glasgow has been very high, 36·8 per 1000. The proportion of deaths under five years to the total mortality rose to the extreme figure of 52½ per cent., this enormous child mortality being due to the coincident increase of measles, whooping-cough, and scarlet fever.

It is announced that Professor G. H. B. Macleod of Glasgow has been chosen a Foreign Corresponding Member of the Académie de Médecine of Paris. He has also been asked to accept the office of President of the Section of Surgery at the approaching meeting of the British Medical Association at Cardiff, but has not been able to accede to this request.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

SEVERAL important alterations in the Supplemental Charter were agreed to by the Fellows at a special meeting held last week; among the rest being the admission of women to the Fellowship as well as Licence of the College. The proposer of this latter resolution, I am informed, did not intend to include the word "Fellow" in the clause admitting them to the Licence in Surgery; but on a division being taken an amendment removing the word "Fellow" was lost by about four votes. There was a good deal of confusion at the time the division was taken, and I am convinced that several Fellows who did not wish to allow women to the higher qualification, but had no objection to their being admitted Licentiates, voted on the wrong side by mistake. The meeting was not so large as might have been expected; probably only about fifty Fellows were present at the proceedings, and not quite forty votes were recorded on any division. The result of this resolution will be that when it becomes law women will not alone be eligible for the Fellowship, but, when Fellows, can be candidates for places on the Council, for examinerships, and for various chairs established by the College, and, lastly, can fill the office of president when elected to that honourable position.

ACADEMY OF MEDICINE IN IRELAND.

A special general meeting of the Academy will be held on Saturday, the 17th inst., to consider the following resolution passed by the General Council:—1. "That it is expedient that a fixed salary shall be paid yearly to the general secretary of the Academy, in consideration of the fact that the editing of the Transactions is part of his duties." 2. "That the salary of the general secretary shall be fixed at £100 a year." 3. "That the following be nominated Honorary Fellows of the Academy:—Sir James Paget, Theodor Billroth, Professor Virchow, Professor Pasteur, Professor Charcot, Dr. Austin Flint, Dr. Keith, Professor Schroeder, Professor Kölliker, Sir Joseph Lister." 4. "That it be recommended to the Academy that application be made to the Government for accommodation in the new science and art buildings."

SCHOOL OF PHYSIC, TRINITY COLLEGE, DUBLIN.

At a meeting of the medical students of this institution held on the 9th inst., it was unanimously resolved to form a volunteer corps on the lines advocated by Surgeon-Major Evatt. It is expected that the latter gentleman will shortly visit Dublin and give a lecture on the subject.

DUBLIN ORTHOPÆDIC HOSPITAL.

The committee of this institution have made arrangements for holding a grand fancy dress ball for the benefit of the hospital, there having been a large outlay consequent on moving to the present premises in Brunswick-street. The ball has been fixed for the second week in February, and will be held under distinguished patronage.

CORK-STREET FEVER HOSPITAL.

Dr. Sydenham Chandlee has been elected resident medical officer and registrar to this institution, in the vacancy caused by the death of Dr. Maturin, to whose lamented decease reference was recently made. The cases of measles in hospital are much beyond the average, and the disease appears to be assuming an epidemic form.

The National Orthopædic Hospital and the Pitt-street Institution have been amalgamated, as the objects of the two institutions are identical and have members of the medical staff attached to both hospitals.

Dr. Stewart, dispensary medical officer of Donaghadee, has been placed on the Commission of the Peace for co. Down.

Dublin, Jan. 13th.

PARIS.

(From our Paris Correspondent.)

THE ACADEMY OF MEDICINE.

DR. BERGERON, of whom I have spoken in my letter of Dec. 13th as having been elected Vice-President of the Academy of Medicine only two months ago, in the room of the late Dr. Fauvel, has passed in the usual course to the President's chair, which he will occupy for the present year; and Professor Trélat has been elected Vice-President in his stead. M. Schultzember has been elected Member of the Academy of Medicine in the Section of Physics and Chemistry, in the room of the late Professor Wurtz.

PLASTIC OPERATIONS ON THE PALATE.

Just before his election to the Vice-Presidentship of the Academy of Medicine, Professor Trélat read a very interesting paper before that learned body on the relative merits of plastic operations on the palate and the use of prothetic apparatus as a substitution for the former. In giving the history of these operations, M. Trélat stated that Roux created staphylorraphy during the latter end of his practice, for he then only operated on small fistulæ, the operation consisting in bringing together the two edges of the gap in the soft and hard palate, in addition to which the patient was obliged to wear a prothetic apparatus. This operation, however, was never practised by him before the patient reached the age of sixteen. A few years later Wolfe performed staphylorraphy in a young girl of ten. Seeing this, several surgeons expressed the opinion that the operation might be performed at a much earlier age. Otto Weber, of Bonn, and Billroth, had recourse to the operation in patients only a few months old. Simon of Breslau operated on an infant of fifteen days old, and Rouge of Lausanne operated on an infant of only a week old. The operations in these conditions were not generally attended with success, which induced Maisonneuve, Larrey, and Nélaton to declare that the results obtained from plastic operations on the palate were far inferior to those obtained from prothetic apparatus. Notwithstanding this declaration by such eminent men, M. Trélat believes in the superiority of plastic operations, though he admits that in certain circumstances prothetic apparatus may be found useful as a *dernier ressort* when the operation has failed, or when the condition of the parts does not permit of one. Moreover, it must be remembered that these apparatus are not always well borne, besides being a source of much trouble and expense to the patient. M. Trélat performed forty-six plastic operations on the soft and hard palate, and from his experience he concludes that these operations should not be performed before the age of seven, nor should they be undertaken when the opening in the palate is too large, or when there would not be sufficient substance in the soft parts. In concluding his paper, M. Trélat insisted on the necessity of submitting children affected by this infirmity to a sort of phonetic education, before as well as after the operation, particularly those who have a wide opening in the palate.

FARADISATION AS A TEST FOR DEATH.

During the recent epidemic of cholera, and owing to the great resemblance of cholera patients to those apparently or really dead, certain physicians advised the adoption of faradisation to distinguish the one form from the other before resorting to interment. Dr. Bochefontaine undertook a certain number of experiments with the view of ascertaining the value of this test. The results he obtained were absolutely negative, in so far that faradisation did not permit one to distinguish real from apparent death.

ANTAGONISM OF THE SYMPATHETIC AND PNEUMOGASTRIC NERVES.

At a recent meeting of the Société de Biologie, M. d'Arsonval read a note from the unpublished papers of the late Claude Bernard on the Antagonism of the Sympathetic and Pneumogastric Nerves, which contains the following conclusions:—1. The pneumogastric nerve is the antagonist of the sympathetic in the abdomen. 2. The pneumogastric plays the same part with regard to the abdominal viscera that the cord of the tympanum does with regard to the salivary glands. In this work M. Claude Bernard equally established the fact that it is at the level of the duodenum that the temperature of the blood is at its greatest height, on the condition, however, that the temperature is taken when the animals are fasting.

UREA IN THE BLOOD.

In a paper on the proportion of urea in the blood, MM. Gréhant and Quinquaud arrived at the following conclusions: 1. The venous blood, returning from the head or limbs, contains no more urea than the arterial blood conveyed to these parts; consequently, any urea from these must be carried away by the lymphatics. 2. Blood which has passed through the spleen or liver contains more urea than arterial blood: the difference is greatest during digestion, and the quantity of urea may reach nine milligrammes in 100 cubic centimetres of blood.

Paris, Jan. 13th.

Obituary.

DR. HERBERT DAVIES, F.R.C.P.

IT is with deep regret that we record the death of Dr. Herbert Davies of Finsbury-square, in the sixty-seventh year of his age. He had for some time been the subject of dilatation of the heart, but it was only during the last year that the well-known consequent obstructions to the circulation had developed so as to occasion serious alarm both in his own mind and to his friends, and which ultimately terminated in most distressing paroxysms of cardiac apnœa.

Dr. Herbert Davies was born on September 30th, 1818, and was the son of Dr. Thomas Davies, a former physician to the London Hospital, who on resigning general practice in the East-end of London went to Paris and studied auscultation and diseases of the chest under Laennec. On returning to London he devoted himself to the study of diseases of the heart and lungs, was one of the first, if not the first, to introduce the use of the stethoscope in this country, and established the special hospital for diseases of the heart and lungs which is now represented by its successor in the City-road.

From 1828 to 1832 Dr. Herbert Davies was educated at North End School, Hampstead, where he became head boy, and used to relate that on occasion of the distribution of prizes he was sent to London to bring up Campbell the poet, who was to preside, and who it was feared might forget his engagement. In 1836 he entered as a student at the London Hospital and matriculated at Caius College, Cambridge, in October, 1838. In the Lent term of his second year he migrated to Queen's College in the same university, and was a scholar and prizeman at both colleges. In January, 1842, he took the degree of B.A. as twenty-eighth wrangler, the year in which Professor Cayley was senior wrangler, and in which the late Charles Kingsley, the present Bishop of Ely, and several other distinguished men took their degrees. His private tutor was Professor Potter, Professor of Natural Philosophy and Astronomy in University College, London. Dr. Davies, in the opinion of his contemporaries, would have stood much higher in the mathematical tripos had he not been disabled for more than a year preceding the examination by an affection of his eyes, which prevented his working by candlelight. In January, 1843, he took his degree of M.B., and in 1844 was elected to the Edwards' Fellowship at Queen's College, and in 1847 to a Foundation Scholarship in the same college. In July, 1848, he took his degree of M.D. After taking his B.A. degree he spent some time in the

schools of Paris and Vienna, and on returning to London became Assistant Physician to the London Hospital in 1845, and subsequently full Physician and Consulting Physician on his retirement in 1874. In his own university Dr. Davies had held the offices of Examiner for the M.B. degree and Assessor to the Regius Professor of Physic, and in the College of Physicians of London, of which he became a Fellow in 1850, he had filled the offices of Examiner and Censor.

From the time of his settling in London Dr. Davies had been actively engaged in professional duties both as a teacher and practitioner. He early showed the advantages accruing from a liberal education and a well-trained mind, and, whether as an observer, teacher, or practitioner, acquired and maintained the reputation of a sound and able physician. Throughout his whole career his character was stamped by an open straightforwardness, high integrity, and Christian faith and principle that could not fail to secure the respect and esteem of his colleagues and all who were brought into contact with him; whilst his genial disposition, urbanity, kindness of heart, and unselfish conduct endeared him to those who had the privilege of knowing him in closer social intercourse. The services that he rendered to the London Hospital, not merely as a physician, but in the active management of both hospital and school, more especially during the cholera epidemic of 1866, were such that he received from the governors a special vote of thanks, accompanied by the presentation of a piece of plate. As a consultant and as medical adviser in the various public appointments that he held, few men could be more worthy of the confidence and regard in which he was held, whether in his professional capacity or as a private gentleman.

The principal of Dr. Davies' professional writings are—(1) "A Course of Lectures on Diseases of the Heart and Lungs," a work which at the time of its publication was an excellent *résumé* of the subject as then known, and shows a critical acquaintance with the diagnostic and pathological views of the German school; (2) "On the Treatment of Acute Rheumatism by free Blistering," a practice which he showed not only afforded great relief to the attendant pain, but also reduced the temperature and shortened the duration of the disease; (3) a paper read before the Royal Society and published in their Proceedings, "On the Law regulating the Relative Magnitude of the Areas of the four Orifices of the Heart," in which his mathematical knowledge was, with great ability, brought to bear in support of his views; this was followed by a second paper on the same subject, entitled "On the Form and Areas of the Heart's Orifices."

Dr. Davies has left a widow, three sons, and four daughters—two of the sons having adopted their father's profession, to uphold, it may confidently be hoped, a name that will have an honourable place in the records of medicine. The funeral took place on Friday last at the Hampstead Cemetery, Finchley-road.

THOMAS BUCHANAN WASHBOURN, M.D., F.R.C.P. LOND.

DR. WASHBOURN, who died on December 11th, 1884, at his residence, Ashmeade House, Gloucester, of Bright's disease and pneumonia, at the early age of fifty-five, was educated at the Gloucester Cathedral School, and commenced his professional studies at the Gloucester Infirmary as a pupil of the late Mr. Thomas Cox Buchanan, from whence he went to Guy's Hospital, where his career was marked with great success. He matriculated at the University of London, and in 1850, at the First M.B. examination, he obtained a gold medal for Chemistry, and honours in Anatomy and Physiology. In 1853 he graduated M.B., and obtained a gold medal for Physiology and Comparative Anatomy, and the scholarship and gold medal for medicine. He became a Member of the College of Physicians of London and graduated M.D. Lond. in 1854, and subsequently, in 1865, he was elected a Fellow of the College of Physicians.

Unfortunately, Dr. Washbourn's health prevented him from commencing practice in London as he had intended to do, and he was obliged to refuse the offer of an assistant-physicianship at his Alma Mater. A long sea-voyage somewhat improved his health, and shortly after his return to England he settled down in Gloucester, where he practised until his death.

Amongst the appointments held by Dr. Washbourn were the posts of Senior Physician to the General Infirmary at Gloucester and the Gloucestershire Eye Institution, Consulting Physician to St. Lucy's Home of Charity and the Children's Hospital, Consulting Physician to the Gloucester Dispensary, and Consulting Physician to the Lydney Hospital. Dr. Washbourn was a J.P., a Trustee of the Gloucester Charities, and in 1859 filled the office of Alderman. Whilst occupying this latter position Dr. Washbourn devoted himself to sanitary matters, and it was largely through his works and influence that the new system of sewers and the public park were obtained for Gloucester. He was the author of "Reports of the Sanitary Condition of Gloucester, 1851 to 1868," and other papers and pamphlets on allied subjects. He was elected an honorary member of the Metropolitan Association of Medical Officers of Health, and Fellow of the Statistical Society; and was also a member of the Anthropological Institute, and a Fellow of the Royal Geographical Society.

THE SERVICES.

Deputy Surgeon-General Alfred M. Tippetts, of the Army Medical Staff, who was mentioned in despatches for his services in the last Afghan War, has been appointed on the Staff of Major General F. Willis, Commanding the Northern District, as Principal Medical Officer. Mr. W. P. Colman, of Brighton, has been appointed Civil Acting Surgeon to the 4th Dragoon Guards, vice Surgeon-Major Ffolliett, removed to Aldershot.

WAR OFFICE.—Deputy Surgeon-General Francis Holton, M.B., half-pay, has been granted retired pay, with honorary rank of Surgeon-General. Deputy Surgeon-General John O'Nial, C.B., to have the local rank of Surgeon-General whilst employed as Principal Medical Officer with the Forces on the Nile.

INDIA OFFICE.—The Queen has approved of the retirement from the Service of the undermentioned officers of Her Majesty's Indian Military Forces:—Deputy Surgeon-General Colvin Smith, M.D., C.B., of the Madras Army; Surgeon-Major Thomas Gray Skardon, of the Bengal Army; Surgeon-Major Horatio David Steel Compigne, M.D., of the Bengal Army; Surgeon-Major Robert Pringle, M.D., of the Bengal Army.

The undermentioned officer is granted a step of honorary rank on retirement:—Deputy Surgeon-General James Alexander Caldwell Hutchinson, M.D., of the Bengal Army, to be Surgeon-General.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen passed the Second Examination for the licence (Anatomy and Physiology) on the 12th inst.:—

Noble, W. H. Francis. | Treharne, Edward
Simson, Francis Taylor. | White, Lancelot Percy.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 8th inst.

Ashley, Sydney Dukes, London Hospital.
Copeman, Sydney Arthur Monckton, St. Thomas's Hospital.
Fox, John Alfred, Guy's Hospital.
Fryer, Charles, Guy's Hospital.
Maudsley, Henry Sydney, St. Mary's Hospital.
Melson, George Hyde, Queen's College, Birmingham.
Pitchall, John Maynard, Westminster Hospital.
Thirkill, Henry, Leeds School of Medicine.
Watts, Alfred Thomas Guy, Cambridge University.

The following gentleman also on the same day passed Primary Professional Examination:—

Gerald Cree, Middlesex Hospital.

CANTOR LECTURES.—The next lecture on "Climat to be given by Dr. Poore at the Society of Arts on Mon next at 8 P.M., will deal with the "Floating Matter in Air and the study of Bacteriology as applied to Climate."

HERBERT MILITARY HOSPITAL.—On the 8th inst fire broke out in this hospital, which caused considera damage to the building, but fortunately was not atten with loss of life.

A HOUSE has recently been taken in Southend the Christian Medical Mission. A trained nurse is to engaged, and the committee hope, when a suitable site been provided and sufficient funds are available, to und take the erection of a cottage hospital.

ST. JOHN AMBULANCE ASSOCIATION.—Advices by last mail report that very encouraging progress is being made at the Victoria Centre of the St. John Ambulance Association; and that the Duke of Manchester and the Governor, Sir Henry Loch, as representing the Chapter of the Order of St. John, had consented to attend a public meeting called to give further impetus to the movement.

QUARANTINE AT MADEIRA.—A telegram has been received by the Union Steamship Company from their agents at Madeira, dated the 10th inst., intimating that the quarantine restrictions which have been in force at that island for some months past have been abolished. Passengers will therefore now be permitted to land as usual without spending some days in the lazaretto.

UNIVERSITY COLLEGE HOSPITAL.—On the 9th inst. a concert in aid of this institution, organised by servants of the London and North-Western Railway Company, took place in the meeting-room at Euston Station. The secretary of the hospital stated that the servants of that railway company had done during the last seven years given £400 to the hospital. The People's Contribution Fund, since its establishment in 1878, had raised £3000 for the hospital. The total in-patients in 1884 numbered 3000 and the out-patients 5000. The concert was most successful, and the proceeds, without any deduction whatever, were handed over to the institution on behalf of which it was held.

A NATIONAL HEALTH INSTITUTE.—A memorial has been forwarded to the Executive Council of the late International Health Exhibition by the Committee of the Manchester and Salford Sanitary Association, suggesting that out of the surplus funds of the late Exhibition an Institute of Health be endowed, such institute to receive the books sent to the late Exhibition as a nucleus of a National Health Library, to carry on the work already commenced in the Laboratory of Biological Research, and to endeavour to co-operate with the Committee of the Parkes Museum of Hygiene and with other sanitary associations for the promotion of the study of sanitary science.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting held on Thursday, January 8th, the following list of officers, Council, and Microscopical Committee was elected. Those marked * did not hold the same office last year. President: Dr. Robert Gee. Vice-Presidents: Dr. J. Drysdale, Dr. J. H. Wilson, *Dr. J. Birkbeck Nevins, *Mr. C. T. Paul. Hon. Treasurer: Dr. James Barr. Hon. General Secretary: Dr. William Alexander. Hon. Secretary of Ordinary Meetings: Dr. William Williams. Hon. Librarian: Dr. J. E. Barton. Council: Dr. J. Grimes, Dr. F. Imlach, Dr. R. T. Owen, Mr. R. N. Pughe, Mr. T. Shadford Walker, Dr. T. E. Young, *Dr. F. J. Bailey, *Dr. J. Cameron, *Mr. Reginald Harrison, *Dr. H. Harvey, *Mr. H. O. Thomas, *Mr. R. Williams. Microscopical Committee: Dr. W. Alexander, Dr. P. M. Braidwood, Mr. H. Briggs, *Dr. Hyla Greves, *Mr. G. Hamilton, Mr. J. S. Hicks, *Dr. J. R. Logan, Mr. Rushton Parker, Mr. P. T. Pope, and Dr. W. Williams.

Medical Appointments.

All communications for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

[illegible] RICHARD J., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Heavitree District of the St. Thomas Union, vice Williams.

[illegible] THOMAS, M.D., F.R.C.P.Lond., has been appointed Physician to the London Fever Hospital, vice Mahomed, deceased.

[illegible] JAMES, M.B., C.M.Glas., has been appointed Resident Physician and Superintendent of Knightswood Hospital, Maryhill, Glasgow.

[illegible] RICHARD, F.C.S., F.I.C., has been appointed Public Analyst for [illegible]

[illegible] FRANK SAMUEL, L.R.C.P.Lond., M.R.C.S., has been appointed Honorary Medical Officer to the Guest Hospital, Dudley.

[illegible] CHARLES H. P. D., M.D., M.Ch.R.U.I., L.R.C.S.I., has been appointed Medical Officer for the Cookstown Dispensary District, vice [illegible] Graves.

[illegible] M.B., M.R.C.P.Lond., M.R.C.S., has been appointed Assistant-Physician to the London Fever Hospital, vice [illegible]

[illegible] JAMES, L.R.C.P.Lond., M.R.C.S., has been appointed House-Surgeon and Secretary to the Scarborough Hospital and Dispensary, vice Young, resigned.

HAW, WALTER H., B.A., M.R.C.S., L.S.A., has been appointed House Physician to Charing-cross Hospital.

HAYDON, WILLIAM RUDALL, M.D., C.M.Glas., has been appointed Medical Officer for the Cruwys Morchard District of the Tiverton Union, vice E. Haydon.

HEATH, JAMES, M.B., C.M.Ed., has been appointed Senior House-Surgeon to the Torbay Hospital and Dispensary, vice Thistle, resigned.

JOLLIFFE, A. R., M.R.C.S., L.S.A., has been appointed House-Surgeon to Charing-cross Hospital.

KIDDLE, Mr. W., has been appointed House-Surgeon to Sir Patrick Dun's Hospital, Dublin, vice G. D. Cowen, M.B., B.Ch., T.C.Dub., L.M.K.Q.C.P.I., resigned.

MAGUIRE, ROBERT, M.D.Lond., M.R.C.P. (late Pathologist to the Manchester Royal Infirmary, and Assistant Lecturer on Pathology in the Owens College), has been appointed Physician to Out-patients at St. Mary's Hospital, Paddington.

MARRACK, WILLIAM, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer for the Bradninch District of the Tiverton Union.

MARRIOTT, JOHN, M.R.C.S., L.R.C.P., has been appointed House-Surgeon to Charing-cross Hospital.

NORRIS, E. STACY, M.B.Cantab., M.R.C.S., has been appointed Medical Officer for the First District of the Windsor Union.

PHILLIPS, SIDNEY P., M.D., M.R.C.P.Lond., has been appointed Junior Assistant-Physician to the London Fever Hospital, vice Gulliver.

SOMERVILLE, JOHN FRENCH, L.F.P.S.Glas., L.A.H.Dub., has been appointed Medical Officer for the Fourth District of the Hollingbourn Union.

THOMAS, B. WILFRED, M.R.C.S., L.R.C.P., has been appointed House Physician to Charing-cross Hospital.

TROTTER, WALTER O., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Pocklington No. 1 District of the Pocklington Union, vice Boissier.

TYRRELL, W. GUY BEAUCHAMP, L.R.C.P.Lond., M.R.C.S., has been appointed Junior House-Surgeon to the Torbay Hospital and Dispensary, vice Heath.

VANN, ALFRED MASON, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Eastern District of the Durham Union, vice Robson.

WALLINGTON, W. T., L.S.A., has been appointed Resident Obstetrical Officer to Charing-cross Hospital.

WHITWORTH, WILLIAM, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the St. Agnes District of the Truro Union, vice Whiteley.

WILLIAMS, WILLIAM MICHAEL, M.B., C.M.Glas., has been appointed Medical Officer and Public Vaccinator for the Pentrefoelas District of the Llanrwst Union, vice Evans, resigned.

WINTER, W. H. T., L.K.Q.C.P.I., has been appointed Medical Officer for the No. 2 District of the Wolverhampton Union.

Births, Marriages, and Deaths.

BIRTHS.

CROWE.—On the 8th inst., at Worcester, the wife of G. Wyndham Crowe, M.D., of a son.

HUTTON.—On the 9th inst., at West-green-road, Tottenham, the wife of Edwin R. Hutton, L.R.C.P. Lond., of a daughter.

JOHNSON.—On the 11th inst., at Kingsland-crescent, N.E., the wife of J. Bovell Johnson, M.D., &c., of a son.

MARTIN.—On the 9th inst., at Chapel-street, Park-lane, the wife of John Henry Martin, M.D., of Cambridge House, Portsmouth, of a son.

MARRIAGES.

DAVY—TUCKER.—On the 6th inst., at Chard, Henry Davy, M.D.Lond., of Exeter, to Beatrice Mary, eldest daughter of Walter J. Tucker, Esq., of Chard.

STANDEN—O'LEARY.—On the 6th inst., at St. Anne's, Moseley, by the Rev. Canon Wilkinson, D.D., assisted by the Rev. J. Leverett, M.A., Vicar, Peter Standen, M.B., C.M., of Stanton-hill, Mansfield, to Frances Jane, elder daughter of John Gibson O'Leary, of the Ferns, Moseley.

DEATHS.

BAXTER.—On the 14th inst., at Weymouth-street, Portland-place, W., Evan Buchanan Baxter, M.D., Professor of Materia Medica, King's College, London.

LANCHESTER.—On the 8th inst., at his residence, Park House, Croydon, of congestion of the lungs, Henry Thos. Lanchester, M.D., F.R.C.S., aged 46.

MANN.—On the 11th inst., at Warltersville-road, Hornsey-rise, N., John Mann, M.R.C.S., L.S.A.L., aged 82.

NUTTALL.—On the 26th ult., at Ayr, N.B., George Robert Nuttall, M.R.C.S., late Bombay Medical Service, aged 63.

ROWLATT.—On the 2nd ult., on board the s.s. *Melbourne*, Dr. William Rowlatt, of Paris, aged 31.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, January 19.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—8 P.M. Dr. G. V. Poore: The Effects of Soil, Drainage, and Vegetation upon Climate (Cantor Lecture).

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. T. Lauder Brunton: Digestive Disorders, their Consequences and Treatment (Lettsomian Lecture).

Tuesday, January 20.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., and on Fridays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Moseley: Colonial Animals.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. President's Address.—Mr. Pepper: Malignant Disease of the Spermatic Cord.—Dr. Norman Moore: Congenital Disease of the Heart; Disease of Sacro-Iliac Joint (card); Drawing of a Renal Tumour consisting of Cholestearine (card); Rupture of the Heart (card); Perforated Aortic Valve (card).—Dr. Charlewood Turner: Horse-shoe Kidney, Sarcoma of both Adrenals (card).—Mr. Davies-Colley: Synostosis of Dorsal Spines.—Dr. Samuel West: Cases of Mediastinal Tumour.—Mr. John Poland: Suppurating Bronchial Gland opening into Œsophagus and Left Bronchus (card).—Mr. Shield: Rectal Polypus (card).

Wednesday, January 21.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour. Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

HOSPITALS ASSOCIATION.—8 P.M. Mr. C. J. Radley: The Relation of the Provident Dispensary to the Hospital.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Special Meeting.—Adjourned Discussion on Dr. Percy Kidd's paper on the Distribution of the Tubercle Bacilli in the Lesions of Phthisis.

Thursday, January 22.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The New Chemistry.

Friday, January 23.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—9 P.M. Prof. Moseley: Fauna of the Sea-shores.

QUEKETT MICROSCOPICAL CLUB.—8 P.M. Papers by Dr. W. B. Carpenter and Mr. F. Parsons.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Althaus: A Case of Hemianæsthesia from Congenital Brain Disease.—Mr. Treves: A Case of Scrofulous Gland Disease with Phthisis.—Mr. C. J. Symonds: A Case of Stricture of the Œsophagus, illustrating a new method of employing the Œsophageal Catheter.—Dr. Hale White: A Case of Myxœdema, with a Post-mortem Examination.

Saturday, January 24.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Dr. Waldstein: Greek Sculpture.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

"THE UXBRIDGE TRAGEDY."

IN consequence of the difficulty we have experienced in obtaining a copy of the full depositions relating to the above case, we are reluctantly compelled to postpone the insertion of Mr. Bowlby's letter, dated Jan. 6th, with comments thereon, until next week.

W. B.—We would suggest that an application be made to the deputy coroner who held the inquiry. Should that be unavailing, the Home Secretary might be communicated with.

Mr. J. W. Watson's complaint should be addressed to the Editor of the "Directory."

MEDICAL OFFICERS OF HEALTH AND PRIVATE PRACTICE

To the Editor of THE LANCET.

SIR,—As the leading authority on professional matters, does it come within your province to give an answer to the following inquiries? 1. Do you consider the medical officer of health for a town containing 50,000 inhabitants should devote his whole time to his public duties, or be allowed to continue his private practice as well? 2. Would his connexion with a hospital for contagious and infectious disease tell for or against his holding such an appointment.—I am, Sir, yours truly,

Jan. 10th, 1885. H. D. F.

*** 1. The question, being to a great extent hypothetical, is not easy to answer. The nature of the answer would also depend upon the competency of the individual. Speaking generally, we would prefer to see medical officers of health independent of private practice; but it is rare to find that a town of 50,000 inhabitants offers a salary sufficient to command the entire services of a really competent officer. Under these circumstances we would rather that a competent officer should be allowed to practise privately than that a less efficient officer should at an inadequate salary, give his whole time to the duties of officer of health.—2. Connexion with an infectious disease hospital is, as a rule, an advantage to an officer of health and to the authority he serves.—ED.

Medico.—1. Perhaps the Lettsomian Lectures now in course of delivery will, when concluded, answer our correspondent's purpose.—2. Application had better be made to the Director-General.

Dr. Purcell.—Yes.

"THE MEDICAL DIRECTORY FOR 1885 AND THE NORTH-WEST LONDON HOSPITAL."

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to state, in reply to the letter of your correspondent, "A Governor of the North-West London Hospital," that the appearance of the names of Sir Andrew Clark and Mr. Christopher Heath as attached to the consulting staff of this hospital was *not* the result of "wrongful information." Both these gentlemen gave their consent when asked a few weeks ago to resume their connexion with the hospital. In deference, however, to the united request of the former staff, they subsequently withdrew their consent, *but not until after the Medical Directory was in the press.* I had already explained this to Sir Andrew Clark and Mr. Christopher Heath. Enclosed is a copy of Sir Andrew Clark's letter to me in reply.

Your correspondent would have shown better taste had he asked for an explanation before rushing into print, and unjustly stigmatising the managers of a public charity.—I am, Sir, yours obediently,

ALFRED CRASKE, Secretary.

North-West London Hospital, Jan. 10th, 1885.

"16, Cavendish-square, W., Dec. 31st, 1884.

"DEAR SIR,—I beg to ackowledge with thanks the receipt of your courteous note of explanation, which is perfectly satisfactory, and I am,

"Faithfully yours,

"ANDREW CLARK, M.D.

A REMEDY FOR THE PHYLLOXERA.

As the result of a number of experiments which have been conducted by Professor Baur of San Francisco, it is stated that a sure cure for phylloxera has been found in quicksilver. The remedy is, according to a report recently issued by Professor Baur, half an ounce of quicksilver, thoroughly mixed with an equal weight of clay, in the soil of the hole in which the vine is planted. The suggestion as to the use of mercury came from the fact that a small globule of that metal in a case of mounted butterflies will protect them against the depredations of beetles, and also to the fact that mercurial treatment is destructive to insects. The report expresses the belief that a dose of the mixture will protect a vine for at least twenty years. The efficiency of the quicksilver remedy has, it is stated, been determined by many experiments which have already been reported upon, and other trials are also being made.

Mr. Lewis Evans.—The lecture originally appeared in the New York *Medical News* of Nov. 22nd, 1884, and was subsequently reprinted by Dr. Bartholow for private distribution.

Mr. H. R. Kerr.—The matter shall have consideration in our next.

THE ENGLISH CONJOINT BOARD.

To the Editor of THE LANCET.

SIR,—I think the enclosed answers which I have obtained from the Secretary and Assistant Secretary of the Royal College of Surgeons in reply to the inquiry whether, having passed the Primary M.R.C.S. and intending to present myself at the Intermediate (M.B.) London next year, I should be able to avail myself of the advantages of the final examination under the conjoint scheme, will interest many beside myself, and therefore trust you will be able to give them a place in your journal.

I am, Sir, your obedient servant,

Jan. 12th, 1885. C. L.

"Royal College of Surgeons of England,
"Lincoln's-inn-fields, W.C., Jan. 3rd, 1885.

"SIR,—With reference to your inquiry of the 12th ultimo I have now to reply to you as follows—viz.: 1. That so far as the subjects of the Intermediate Examination of the University of London comprise the subjects of the first examination under the Examining Board in England by the Royal Colleges of Physicians and Surgeons, so far will you be exempt from passing such first examination. 2. That, as it would appear that Pharmacy is not included in the Intermediate Examination, you will have to pass in that subject to complete what will be required of you under the combined examination before admission to the final examination of the Board. 3. And that you will learn from the enclosed Regulation what are the other conditions applicable to your case. "I am, Sir, your obedient servant,

"EDWARD TRIMMER, Secretary."

"EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS.

"Any candidate for the Licence of the Royal College of Physicians and the Membership of the Royal College of Surgeons who shall have commenced his professional study before Oct. 1st, 1884, shall, on production of the certificates required by both Colleges when he commenced his professional study, and on payment of the required fees, be admissible to either or all of the examinations of the Examining Board. Any candidate who shall have passed before the 1st October, 1884, at either of the two Colleges, the first or second examination, or the first and second examinations, will be exempt from the equivalent examinations of the Examining Board."

"Royal College of Surgeons of England,
"Lincoln's-inn-fields, W.C., Jan. 10th, 1885.

"SIR,—In reply to your further letter of the 5th inst. I have to acquaint you that you will be required to pay the fee of ten guineas required for the first examination when you present yourself for examination in Pharmacy. I have to add that had you passed in that subject as well as in other subjects elsewhere, you would nevertheless have been required to pay the same fee.

"I am, Sir, your obedient servant,

"FRED. G. HALLETT, Assistant-Secretary."

A MIDWIFERY COINCIDENCE.

To the Editor of THE LANCET.

SIR,—The following may be interesting to some members of the profession:—In November last a woman called on me, and asked me if I would attend her two daughters in their confinements, her elder daughter expecting her second child and the younger being a primipara. She also informed me that as they lived at different parts of the town, she could not be with both at the same time to nurse them, and had decided to have them at her own house until they were safely delivered and ready to return home. I asked her when she expected them to be confined. She replied, "The first week in December." I said, "What, both in the same week?" Her answer was, "Yes, the same week and the same day;" and I added, "Perhaps the same hour." Her response was in the affirmative. On Dec. 3rd I was called to the house; I went upstairs and delivered the younger daughter of her first child. All being satisfactory, I descended to go home, when I was met by the elder daughter, who informed me that she felt unwell, and asked me to look at her. I reascended with her, and in the course of the following half-hour safely delivered her of her second child, and thus fulfilled their mother's expectations. Both mothers did well, and in due course returned to their respective homes.—Yours very truly,

Hillsboro', Sheffield, Jan. 13th, 1885. WILLIAM JOHN SUMNER.

A LADY OVARIOTOMIST IN CHINA.

WE take the subjoined clipping from the *North China Daily News* of Nov. 27th, 1884:—

"The formidable operation of ovariotomy was performed in Shanghai on the 25th ult., for the first time successfully in North China. The operator was Miss Elizabeth Reifsnyder, M.D., of the American Woman's Union Mission. Dr. Reifsnyder has in course of construction a hospital for native women, designed, with all the most recent improvements, by Mr. F. M. Grattan of Shanghai. For the case referred to she was obliged, as her own hospital has not yet been opened, to seek the good offices of the doctors attached to St. Luke's Hospital, Hongkew. A suitable room was specially prepared, and the result has amply rewarded the trouble taken. A tumour weighing more than a fourth part of the patient's entire weight (33 lb. out of a total weight of 114 lb.) was removed, and the woman is now ready to leave the hospital, perfectly recovered. The patient in this instance came from the interior of the An-huei province, a distance of more than 500 miles, attracted by reports of foreign surgical skill, and it is not too much to hope that this remarkable success will help to spread the renown of foreigners, and will bring within the reach of foreign aid a class of people and a class of cases which have hitherto held aloof from the hospitals in which advice and assistance can be obtained only from men."

We understand that ovariotomy has been performed some half-dozen times at mission hospitals in South China. The results have been anything but encouraging; a fact not to be wondered at when the broken-down condition in which patients with chronic diseases are always brought to foreign hospitals in China is remembered.

MEDICAL EXAMINATIONS AT OXFORD.

To the Editor of THE LANCET.

SIR,—Kindly permit me, through the medium of your columns, to draw attention to the above subject, in the interest of present and future Oxford men. As many of your readers are aware, the opportunities for entering the medical profession at Oxford are conspicuous by their absence; and the path is made as thorny as possible by the restrictions put upon us by that worthy, if somewhat privileged body, "The Board of Medical Studies." The particular grievance to which I now wish to draw attention is the length of time that is allowed to intervene between two examinations. At Cambridge the examinations are held at intervals of six months or so, so that if a man has the misfortune to be "ploughed" he can go up again at the end of that time should he feel disposed. At Oxford, on the other hand, examinations are held but once in the year, and an unsuccessful candidate thus has to wait twelve months before he is allowed again to trouble the examiners. This long delay I maintain is both unnecessary and a hardship, more especially with regard to the first examination, which mainly consists of anatomy and physiology. At the "Primary" College of Surgeons a man to be "referred to his anatomical and physiological studies" for six months is an exception, and he is rightly considered to know very little about his work; the ordinary reference is for three months only. Is it not, then, a great disadvantage to the Oxford man—who is, I fancy, as a rule, quite equal in ability to the College of Surgeons candidate—that such a long time should elapse before he can try his hand again at his 1st M.B., and especially in these days when medicine and surgery require such a great share of the time at his disposal. Trusting that this letter will attract the attention of some of the responsible authorities at Oxford,

I remain, Sir, yours truly,

Jan. 13th, 1885. B. A.

RAMSGATE CORPORATION BILL.

To the Editor of THE LANCET.

SIR,—I would not trespass upon your space had not the subjoined extract from the proposed Ramsgate Municipal, or rather Corporation, Bill afforded amongst us considerable amusement, as it may, I trust, amongst your readers.

The "Council" propose to bring forward this particular Bill before Parliament next session. I will not enter into the merits of the same, but simply quote the following extract (Part I., Section 5):—"'Infectious disease' means and includes small-pox, cholera, typhus, typhoid, scarlet, and relapsing fever, and diphtheria, and such other diseases as the Corporation, under the provisions and for the purposes of this Act, *may from time to time declare to be infectious.*"

I should fancy the medical officer of health might have something to say upon the subject. Imagine, Mr. Editor, for one instant our borough magnates sitting in solemn conclave, each with a medical encyclopædia in hand, working out the question of tweedledum and tweedledee—bacteria, bacillus, and all the germs. I think that whoever drew up the draft of the proposed Bill might, at least, have had the courtesy towards the town's most excellent medical officer, and to the profession generally, to have added, "as we are by our medical officer or officers of health advised." I suppose the Corporation (last year first incorporated) were so taken up and entirely engrossed with their own magnitude—municipal improvements, "drainage schemes"—that in drafting the Bill now quoted from they forgot that there is a certain quantum of respect due to the medical profession. In these degenerate days it is very wonderful how forgetful are these corporations, local boards, &c.

I am, Sir, yours truly,

CHARLES CHITTENDEN,

Ramsgate, Kent, Jan. 10th, 1885. Late Surgeon R.N.

COLOUR BLINDNESS IN GERMANY.

UP to April 1st, 1883, 139,452 railway *employés* were examined in Germany with reference to colour blindness. It was found that of these 998 had no idea of colour. Of 115,154 engaged in the general work of the service, it was ascertained that 46 were completely, and 273 partially, insensible to differences of colour. Among 13,616 engineers one only was completely, but 27 others partially, in the same case.

Mica.—Professor Liveing, Cambridge.

Mr. D. Jones must apply to the deans of the respective schools.

THE PHYSIOLOGY OF THE FEET.

To the Editor of THE LANCET.

SIR,—There seems to be a difference of opinion among experts as to how people walk normally—that is, with heelless shoes, or when barefooted. During a recent journey in the mountains I observed particularly scores of natives, plain-men, and hill-men of various nations. Invariably the heel first touches the ground, but there can be little or no shock on impact, and the sole of the foot is planted immediately afterwards; and as few natives step out straight-kneed, there is a more gliding motion than in Europeans. I myself often use heelless sandals; but walking straight-kneed I notice, especially at the beginning of a march, the shocks sent by each step up the spine, for which reason, when going down hill, I plant the whole foot flat, or even the toes rather first. This affords more security against slipping. Natives walking with slightly bent knees avoid these shocks, and as most of them carry loads this is important. In going down hill they also plant the foot nearly, but seldom quite, flat. I do not include in these statements those whose worn out or very loose grass shoes compel them to drag their toes along the ground. I am, Sir, yours truly,

ARTHUR NEVE, F.R.C.S.Ed., &c.

Kashmir, N. India, Nov. 20th, 1884.

MACARONI INFECTION.

To the Editor of THE LANCET.

SIR,—It is doubtful whether we ought to eat macaroni this year as usual. When I was at Naples some time ago it seemed impossible ever to touch it again; but I was assured that all sent to England was made in clean manufactories, and was not that which we saw drying by the roadside all along the way to Pompeii. Still, one feels that with cholera raging both at Naples and Genoa during the past summer everything must have been contaminated; though on inquiry at one of the principal Italian warehouses I find that no special precaution has been taken in buying their stock. A guarantee that such a useful and wholesome article of food need not be excluded from our bill of fare would be acceptable. I am, Sir, yours truly,

Bournemouth, Jan. 13th, 1885. W.

An Anxious Father should consult his medical attendant. We do not give medical advice.

Clinical Lectures
ON
CASES ILLUSTRATING RENAL SURGERY.

Delivered at University College Hospital,

BY ARTHUR E. BARKER, F.R.C.S.,
ASSISTANT PROFESSOR OF CLINICAL SURGERY AT UNIVERSITY COLLEGE, AND ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE II.

GENTLEMEN,—The next case is also that of a child, and illustrates in the first place the difficulty of diagnosis of certain renal affections, and in the next the freedom with which the kidney may be dealt with in exploratory operations without risk to the patient. I may remark here that this point was far less known when this case was operated upon, nearly three years ago, than it is now, for since then many similar exploratory operations have been performed and data have accumulated.

The points I wish particularly to emphasise may be summarised in the title which follows:—

CASE 2. *Complete History of Renal Calculus; Exploratory Lumbar Incision, with Palpation and Multiple Acupuncture of the Kidney; no Stone detected; Operation Wound healed in a few days, with no ill effects.*—A. G——, aged nine years, was admitted into University College Hospital, under my care, on Jan. 23rd, 1882. Previous to this he had been treated for renal calculus both at Ormond-street and at St. Peter's Hospitals. His illness appears to have dated back three years, when his parents first noticed that he had pain and difficulty in micturition. He was then circumcised at the Children's Hospital; but a little later the additional symptoms of pain in the right side and hæmaturia were noticed. He was then taken to St. Peter's Hospital for Stone, where he remained for about a month, during which period he was several times sounded for calculus in the bladder, with a negative result. The rest in bed, however, seemed to check the bleeding, but the pain in the loin was as bad as ever. After this I admitted him into hospital to observe his case, and here again the rest seemed to relieve him almost completely, and he left the hospital accordingly soon after. Again, however, he was readmitted on Jan. 23rd, 1882, all the symptoms having returned. They are noted as follows in the hospital register:—"Paroxysms of pain gradually increasing in intensity, and felt in the loin and tip of the penis. During the pain there is severe retching, but no actual vomiting. The urine is not always bloody after the attacks of pain, but is usually lighter at first, and then becomes darker and darker and thicker, resembling pure blood at times; micturition five to six times daily; no history of increased frequency at any time. The bowels are stated to be much relaxed after taking hot food. The boy has always been delicate, and suffered much from bronchitis as an infant; his father is also asthmatic and catarrhal, as are the other children of the family, but the mother is healthy."

On Jan. 31st I examined the flank with the hand carefully, as also the bladder and ureter through the rectum, the boy being under the influence of chloroform, but could find nothing abnormal anywhere. The urine passed immediately after this was very clear, but that voided the night succeeding was dark reddish-brown, containing blood and white corpuscles and oxalate of lime crystals. The next day the boy seemed very well. On Feb. 3rd, it is noted that the urine just passed was more bloody than any seen yet. It was acid, of a specific gravity of 1025, and contained crystals as before. In other respects the general health was good, and there were none of the paroxysms of renal colic formerly complained of. Here, then, there appeared to be the completest evidence of renal calculus, hardly a symptom, as usually described, being absent. In the first place, there was pain in the right renal region of a very severe character, paroxysmal and running down to the tip of the penis, and followed by severe hæmaturia. The urine at the same time was acid, and contained crystals of oxalate of lime and red and white corpuscles. The fact of the kidney not being enlarged excluded new growth, as the symptoms dated back three years, and appeared to negative tubercular disease of the same standing. Either of these diseases existing for three years would almost certainly have been accompanied by enlargement of the kidney. Then, after manual examination of the loin, there was an increase of hæmaturia the next day. There was not, however, any increased frequency of micturition at any time, so far as we could make out, and this was the only symptom of calculus absent.

It appeared therefore that, everything having been done by ourselves and at two other hospitals to mitigate the sufferings of the child without avail, the proper course to pursue was to cut down upon the kidney, explore it carefully, and if possible, remove the stone, if present, from it. With this object in view, I cut down upon the kidney on February 8th by an oblique incision running from above and behind the tip of the twelfth rib downwards and forwards. To gain room the tip of this rib was removed with bone forceps. I now passed my finger over both surfaces of the kidney, but found nothing abnormal. I then punctured the organ in all directions about twenty times with a long needle passed deeply, but with a like negative result. As I could not decide to remove a kidney in which nothing was to be discovered abnormal, I closed the wound. This was one of the first cases in which this mode of exploration was adopted in this hospital, and the effect of it was watched with much interest. There was very little difficulty in it. Only one muscular vessel required ligature and the punctures of the kidney hardly produced any bleeding. The palpation of the organ, which was small and highly placed behind the ribs, was the only matter of any trouble. In the exploration I used every antiseptic precaution except the spray, and after suturing the wound covered it with lint and carbolic oil and a pad of dry salicylic wool, a small drain-tube having been inserted in the lower angle.

The next day there was little to note except slight tenderness in the side and uneasiness. Temperature 99·8°; pulse 144 to 155. The following night the patient slept better, and was brighter the succeeding morning. Temperature 100·6°; later 101·3°; and at 6 P.M. 99·6°. He had passed sixteen ounces of urine in twenty-hour hours, with some pain at the tip of the penis, but far less than before. The urine passed at 6.30 last evening was light-coffee coloured, with thin ropy deposit and very acid; sp. gr. 1032. That passed at 1.30 A.M. was lighter still, and strongly acid; and that voided at 8 A.M. was still lighter, and had only a slight tinge of blood; sp. gr. 1034.

The wound was dressed for the first time on Feb. 10th, and was found quiet, with only a trace of odourless serum around the tube, which was removed; it was dressed as before. On the 13th there was a slight pain in the flank after a meal consisting of mutton chop and bread. At 2 P.M. he passed some very thick alkaline urine of deep reddish-brown colour, with deposit; sp. gr. 1032. By the 14th he had got over all the effects of the operation, and had been sitting up in bed for some days. There was very little pain in the side, but some after micturition. The urine about this time was only a little smoky, with red and white corpuscles in fair amount and oxalate of lime crystals. On the 17th he seemed quite well, but the urine remained as before, and there was still pain in the side. On the 21st I removed the wire sutures, as the wound had healed by first intention. On and after the 27th he was out of bed and running about, all pain, both in the side and penis, having disappeared, and except for paleness he looked very well. He went to Eastbourne on March 1st, having no pain anywhere. The urine at this time was 1025 and acid, with a slight trace of albumen, due no doubt to the presence of blood.

It is worthy of remark that from this time onward for a considerable period the patient was free from all lumbar or other pain, and only noticed a little blood in the urine. This has been noticed since in other cases. When he returned from the seaside he looked well and hearty, and remained so for some time. A few months later, however, he seemed to fall off in health, and with this there was a return of the old symptoms. He was then readmitted into the medical wards for observation, but nothing new was discovered. Rest, good diet, and tonics appeared, however, to benefit him, and the symptoms became less severe. Since his discharge I have not seen him.

In considering this case in the light of further experience I am inclined to think it possible that, although the symptoms appeared so typical, we may have had to deal here, not with a renal calculus, but with a small tubercular deposit, or ulcer, in the pelvis or ureter. I cannot help

thinking that the two conditions in their early stages may give rise to identical symptoms. In a later stage we know that they closely resemble each other in their manifestations. Of this I have had an excellent illustration quite recently in a case admitted into hospital in an almost dying state. The symptoms might either have been held to indicate renal calculus or tubercular pyelitis. On the death of the patient (a man aged about fifty), soon after I found well-marked tubercular disease of the right kidney, right ureter, right vesicula seminalis, and of the epididymis of both sides. The deposits were caseating, but not very much broken down. The left kidney was sound. Be this as it may, we learn from the foregoing history that even with the most complete history of renal calculus, and with all the assistance of our recently devised lumbar incisions and explorations, we may yet be baffled in detecting a stone in the kidney when we actually have the organ between our fingers. Either this, or there is some other condition beside the presence of a stone which can give rise to identical symptoms. On the other hand, a sufficient number of cases are now on record, where with such a history and exploration a stone has been found and removed, to justify a resort to such a proceeding even in doubtful cases. And this appears distinctly to be our duty when we consider how devoid of risk the measure is when employed with care and all antiseptic precautions. You will observe that this little boy, far from being in any way injured by the exploratory operation, was actually known to have been relieved of some of his most distressing symptoms for some months afterwards; and though we cannot definitely put this down to the credit of the operation, it is, at all events, satisfactory to observe the fact, especially as it has been noticed in several cases of the same exploration since undertaken.

CASE 3. *Pyonephrosis; Aspiration of thirty-six ounces of Pus; Relief; subsequent Re-accumulation, then Rupture of the Collection into the Sheath of the Psoas Muscle, with pointing in Scarpa's Triangle; Nephrotomy; Drainage of large quantity of Pus from the Kidney; Relief.* — This case is of a somewhat different kind, and illustrates points which are sufficiently indicated in the title affixed to it, to which I invite your attention. It is chiefly remarkable for the fact that a large pyonephrosis eventually made its way along the sheath of the psoas muscle, and so into Scarpa's triangle, taking, in fact, the same direction precisely as an ordinary psoas abscess from spine disease, a most unusual course for a renal abscess, which usually forms in the loin and points somewhere above the crest of the ilium. It is also noteworthy that whereas before the incision was made into the kidney only a slight trace of pus was found in the urine, some time after the operation the ureter became more pervious, and pus was passed freely by the urethra. During July, 1884, it escaped from the lumbar sinus and bladder alternately about every other day, ceasing almost completely to come one way when abundant the other. Another point is perhaps suggested here—namely, whether it is an advantage to the patient that the perviousness of the ureter should be re-established where there is a suppurating kidney. In this case the appearance of pus in the bladder in considerable amount some months after the nephrotomy, during which the patient's health was materially improved, was soon followed by the occurrence of pain in the kidney opposite to that first affected. This pain seemed for a time troublesome, and was accompanied by tenderness on palpation and other symptoms mentioned below, the patient's health at the same time appearing to fall off. All this suggested to me the possibility of the other kidney becoming secondarily affected from irritation in the bladder due to the pus passing that way, it being impossible to keep this pus perfectly sweet for months with an open sinus in the loin in a patient up and going about out of doors. The case also suggests a limit of operative interference for pyonephrosis, based upon evidence pointing, it is believed, to unsoundness of the opposite kidney, or, at all events, arousing grave suspicion as to its healthiness. The case is briefly as follows:—

A. F——, aged forty-eight, originally a shoemaker, now a porter, was admitted into University College Hospital, under the care of Dr. Roberts, on Jan. 21st, 1884. At this time he had a large lumbar swelling, with all the characteristics of an accumulation of fluid in the kidney, and which was diagnosed to be renal, on the same grounds generally as those given in Case 1. There was a history of an attack of inflammation of the kidneys two years before, which compelled the patient to keep his bed for eight weeks, during which time the urine was very thick; otherwise his general health, past and present, was noted as good. His viscera and all secretions except the urine were normal, the latter containing a slight cloud, which showed corpuscles, but only a trace of albumen and no sugar; its specific gravity was 1014, and the average percentage of urea for ten days only 1·6; the temperature was 99·4°. Soon after his admission Dr. Roberts kindly asked me to see the patient, and I had only to endorse the view that this was a renal swelling, and to suggest that it was a pyonephrosis; I therefore aspirated the collection from behind at the point mentioned in Case 1, and drew off thirty-six ounces of laudable inodorous pus on Feb. 6th. No calculus was felt by the needle. After this the man lay in bed for seventeen days, and during this time the sac did not refill. He seemed so much better that on Feb. 23rd he was allowed to go home, with directions to return from time to time for observation. A few weeks later it was clear that the sac was filling again, as was expected. By the middle of March I was surprised, however, to find that not only had the pyonephrosis returned, but that it had given way, and now stretched from the flank to Scarpa's triangle under Poupart's ligament, fluctuating the whole way. This offered a remarkable contrast to the previous condition, where the sac was sharply defined below, and indicated that the collection had most probably burst into the sheath of the psoas muscle.

As the patient was now beginning to suffer again I readmitted him on March 31st with the object of drawing off the pus by incision in the loin. Accordingly, the patient being under the influence of ether, on April 2nd I made an oblique incision three inches long midway between the last rib and the iliac crest downwards and forwards, through skin, muscles, and fascia. Reaching the sac I opened it with a firm thrust of my finger nail, and gave exit to twenty ounces of pus. This opening led directly into the pelvis of the kidney, and with the finger I and my colleague, Mr. Godlee, could feel the calyces of the organ. A probe passed inwards and downwards reached nearly to the groin, but nowhere was a stone to be found. As the drainage from the loin seemed sufficient, I did not think it necessary to make a counter-opening in Scarpa's triangle, but placed a large tube in the lumbar opening before partially stitching it together. Very little blood was lost during the operation, which was conducted under strict Listerian precautions. There was a moderate amount of shock on the same evening, the temperature falling to 96°, but on the following morning the patient is noted as being very comfortable. Pulse 80; temperature 99·6°. The wound was dressed on the 4th and looked well, the general condition being also good. On the 5th the patient was sick several times, complained of pain in the hypogastrium and around the umbilicus and did not look at all well, the temperature being 101°; his urine was almost black from carbolic acid and contained a little above the normal percentage of urea—namely, 2·8 on the whole amount. This, however, only equalled twenty-three ounces in twenty-four hours, making only about 310 grains of urea excreted in the same time. The patient, however, was below the average weight and size and, it must be remembered, was in bed on restricted diet. (His weight was 120 lb., and he ought to have been eliminating about 400 grains of urea.)

On the 7th all the above symptoms had disappeared, and the patient looked very well. The dressing was changed under the spray. On the 8th there was again carboluria, with a slight rise of temperature, but the other symptoms of carbolic intoxication were absent, and he passed forty-seven ounces of urine, with a specific gravity of 1020, and a percentage of 1·85 of urea, or about 407 grains in twenty-four hours. The condition of the wound from this date on requires no comment. It healed up to the drainage opening quickly, and the patient was soon able to get up and go about, wearing a Listerian dressing of gauze, &c. At the beginning of May he was sent to the convalescent home, still wearing an antiseptic dressing as before. After the operation the temperature was satisfactory throughout, except on April 4th and 5th, during the period of carbolic intoxication, when it rose to 101°, falling again with the disappearance of the symptoms. Again, on the 7th, after the second dressing, it rose to 100°, corresponding to the reappearance of the carboluria; after this it was only 99·4° once, but usually normal, until he left the hospital.

When the patient returned from Eastbourne a month later, at the beginning of July, he looked very well indeed, and continued so for a time, the fistula in the loin being still

open. Then, being out of work and not having an abundant diet, he seemed to lose strength again. At the beginning of August I readmitted him for observation and to see whether anything could be done to get rid of the sinus in the loin. I found, however, that there were but two courses open to us, only one of which could be regarded with favour—viz., either to encourage closure by rest and the free drainage of the part or to remove the kidney. The latter idea I abandoned at once, for the following reasons:—First, the patient seemed to have lost strength lately; again, his temperature had, after August 4th, regularly risen each evening two, or even three, degrees, to fall again, though not quite to normal, in the morning; there was nothing about the wound or abscess to account for this. He now also began to complain of a good deal of pain in the left flank, with some tenderness on palpation in the left renal region. This pain radiated down the left thigh and testicle, and was at times described as severe. There was now no pain or tenderness on the side operated on. At this time, too, he began to complain of scalding on micturition and to pass more pus than before, with acid urine, which contained besides a good deal of phosphates. The pus when coming from the sinus was diminished in the urine, and *vice versâ*. All this—together with the fact that the percentage of urea had originally been below normal before the operation, and was now, after all immediate effects of the latter had passed off, still below, being only 1·3 on an average of ten days—led me to suspect that the opposite kidney was also not sound. This surmise, of course, if accurate, contra-indicated nephrectomy. The patient left the hospital on Saturday, September 27th, and with none of the symptoms mentioned above very prominent; but for the weakness due to confinement to bed there would have been no reason for his not following his calling. For the last ten days of his stay in the hospital (September 14th to 24th) the amount of urine passed in twenty-four hours was very constant, the average being only 32·2 ounces; the specific gravity was steady each day at 1025; the percentage of urea was also perfectly constant, at 1·9 for every twenty-four hours—this gives an average of only 293·6 grains of urea for each of the ten days. The temperature was above normal, showing usually a slight rise each night. The morning average was 100·3°, the evening 100·4°, for the last ten days; but the difference between morning and evening was usually more than this average showed. (This diminished elimination of urea in spite of the presence of pyrexia is worth noting as part of the evidence, in all probability, of derangement of the excretory power of the left kidney.) The urine was still slightly turbid from the presence of pus, but when this subsided it showed no evidence of the presence of albumen. It was *still* foul to some extent, though acid again, having been until lately either neutral or alkaline. The fact that the patient suffered considerably from carbolic intoxication on very slight provocation is also worth noting, and, taken with other facts, lends support to the view that the left kidney was probably inadequate to any great extra strain thrown upon its eliminatory functions.[1]

We now turn to another case offering a different class of phenomena for consideration.

CASE 4. *Tubercular Kidney; Extreme Prostration; Exploratory Nephrotomy; Drainage; Considerable Improvement for some months; subsequently Amyloid Disease of Opposite Kidney and other Internal Organs, and Death from Asthenia five months later.*—Regarding the following case the conclusion is, I think, justified that the limit of operative interference was reached in dealing with it. To have gone further at the time the patient first came under surgical treatment would almost certainly have led to a fatal termination, whereas what was done may fairly be held to have improved the health, relieved suffering, and prolonged life.

The patient, A. P——, aged twenty-seven, was admitted into University College Hospital on May 12th, 1880, under the care of Dr. Bastian. Her history was that she had begun to lose health about six months before (Sept. 1879). She suffered then from weakness, great headache, occasional shivering, anorexia and diarrhœa, to such an extent as to be obliged to give up her employment as governess; she had been losing ground ever since. She described symptoms, noticed at the age of seventeen, extremely like those due to the passage of a renal calculus, and since then there has been frequently a "brick-red" sediment in the urine. The same symptoms were noticed last August, and at that time there had also been pain in the loins from the last rib to the nates, with thirst, diminished flow of urine, and abundance of "brick-red" sediment. Then at the end of September she noticed a lump in the right side of the abdomen rather larger than an egg, slightly tender on pressure. This remained about eight weeks, and then gradually went away. During its presence she had occasional sickness, increased frequency of micturition, with pyuria, and also diarrhœa. Since January no pus had been seen in the urine, and the tumour had quite disappeared. But in February her left thigh and leg became very much swollen, tender, and itching, and shortly after the right limb became similarly affected, with much loss of power besides. She was admitted into hospital on March 12th, 1880.

At this time she was very emaciated and anæmic, and her lower limbs were as described, the veins being marked out and hard besides. The nervous and respiratory systems showed nothing abnormal. The pulse was 128, regular in force and rhythm, and compressible. The abdominal organs appeared normal to palpation, except for a fulness in the right flank extending to the iliac fossa, where its margin was distinct. This tumour was not painful on pressure, and there was resonance over it in front. The urine was 1020, slightly alkaline at first, but acid later. It contained no albumen or sugar, but deposited a little mucus. There was still much headache. Her family history was good.

With rest in bed, care in diet, and other general treatment, some improvement took place in the patient's condition; at first she became less anæmic, the swelling in the legs became much better, and she felt stronger, the headache, however, being still distressing at times. The temperature rose nightly, often to between 103° and 104° with striking regularity, and was normal in the morning. On April 6th the patient had a rigor. On April 21st I was kindly asked to see her, and endorsed the view that the tumour in the right flank was renal, and probably contained pus and a stone. I therefore explored it with an aspiration needle through the loin in the usual way, and at a moderate depth struck a collection of the most fetid pus, of which I drew off an ounce and a half. On thrusting the needle a little deeper, nothing but pure blood came away, and no calculus was felt. No ill effects followed this exploration, and no pus or blood was seen in the urine. The condition remaining as before, I cut down upon the kidney from the loin a week later, on April 27th. On reaching it, an aspiration needle was thrust into the organ, and some pus again evacuated. Along this needle I passed a knife, and through the opening thus made my finger, which I thrust into the pelvis of the organ. Pretty free bleeding resulted for a few moments, but then ceased. No calculus was felt, and the pelvis of the kidney was found to be smooth wherever it was reached. The strictest Listerian precautions were observed. This operation produced considerable shock in the weak condition of the patient, from which, however, she recovered fairly rapidly. On the same evening the temperature rose as usual, and reached 103°. The next morning it had fallen to 95·2°, and only rose to 97·2° at 10 A.M.; from this on for twenty-four hours the average taken in the axilla and rectum every two to three hours was 95·5°, and it then only very slowly rose until in twenty-four hours more it had touched the normal again. After this it remained nearly normal for five days, and then rose as before in the evening, but not within two degrees of the usual evening temperature before the nephrotomy. Indeed, to the termination of the case the temperature was shown to be permanently modified for the better by the drainage of the suppurating kidney. All the subnormal temperatures were verified by repeated observations with different thermometers. The patient's general condition during the period of very low temperature seemed but little affected, but a few days later it appeared much improved. She was brighter and ate and drank with more relish and was soon able to sit up a little. On the whole the nephrotomy may be said to have produced marked benefit for a time. The urine throughout remained almost normal, only showing a trace of albumen; the legs became less œdematous and gained strength, and the patient could soon sit up. All this time the wound drained well but showed no tendency to close

[1] NOTE, Jan. 20th, 1885.—I saw this patient last week, and examined him. He says he is better, and feels no pain in either flank. The urine looks normal, and has been so for some time; it has no deposit. There is no tenderness in the renal region on either side on manipulation. There is still a very small sinus in the right loin, which secretes a drachm or two of pus in the day. The patient is thinner than when last seen, but this may be accounted for, perhaps, by his diet.

from below, and a probe still could be passed downwards and inwards towards the ureter for a distance of eight inches. On passing my finger into the wound its whole length nothing in the shape of a deposit or stone could be felt on any occasion.

In this case the question was several times debated whether the kidney ought to be removed; but to this measure I was strongly opposed on account of the weakness of the patient and the fact that the swelling in the lower limbs probably indicated some thrombosis of the larger systemic veins, due to causes not yet discovered, but still undoubtedly grave; besides this, there was slight albuminuria; and I am confident now that attempt to remove the kidney would have had a fatal result. The subsequent history of the case may be briefly summed up. In the early part of June the patient became listless and dull, taking but little interest in things around her and giving up reading; she also became irritable and careless about passing motions and urine in the bed; diarrhœa also became a prominent symptom. The superficial veins on the right side of the abdomen and groin became much dilated, those of the left slightly so. From June 30th albumen was found in the urine in steadily increasing quantity, only a trace having been present before. Later on (July 20th) casts, hyaline, granular, and epithelial, were found. On July 26th there was an attack of convulsions, ending in stupor. Two days later another fit, with increased stupor and weakness, was noticed, and again on the 29th. On the 30th there was some sharp bleeding from the sinus, and she died at 3 A.M.

The autopsy, made by Dr. Barlow during my absence from town, shows how well justified was the conclusion that removal of the kidney would have been an improper operation in this case as it presented itself to us. The brain was generally healthy, though the sulci were abnormally wide and the convolutions somewhat wasted. The heart showed small vegetations on the aortic, and some larger ones on the mitral, valves, otherwise nothing abnormal. The lungs and pleuræ were fairly healthy, showing no tubercles. The liver was healthy. The spleen was enlarged and markedly amyloid. The left kidney was much enlarged and notably amyloid, the cortex being fatty and increased in depth. The right kidney, which had been operated on, was firmly adherent to its surroundings, including the cæcum and ascending colon. It was hollowed out into several rough tuberculated spaces, into one of which the lumbar wound entered, and all its secreting substance seemed destroyed. The ureter was also rough and lumpy. This kidney contained some greenish pus, but no calculus. The renal vein was filled with a soft cheesy thrombus, which extended into the vena cava upwards nearly to the heart, and downwards for about three inches.

A sufficient explanation of the gravity of this case from the first is furnished by these notes without further comment.

ABSTRACT OF

Lettsomian Lectures

ON

DISORDERS OF DIGESTION,

THEIR CONSEQUENCES AND TREATMENT.

Delivered at the Medical Society of London on Monday, January 19th, 1885,

BY T. LAUDER BRUNTON, M.D., F.R.C.P.,
ASSISTANT-PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE II.

BILIOUSNESS and indigestion are terms used so frequently together that we do not always sufficiently distinguish between them. Biliousness is, in all probability, of complex origin. The difficulty we have in ascertaining the exact causation of biliousness is no doubt largely due to the fact that disturbance of the liver affects the stomach and intestines, and *vice versâ*. The arrangement of the bloodvessels in the liver and alimentary canal accounts for the close connexion of these structures. Dr. Brunton has found, by a number of experiments on the artificial circulation of blood through the livers of rabbits, that the liver is highly elastic. When the bottle containing the blood was raised two or three feet above the liver, so as to increase the pressure under which the blood flowed through it, the organ expanded almost like a sponge, and again contracted when the pressure was diminished. In the experiments the rate of flow from the hepatic veins was very variable; the rate appeared to depend upon the quality of the blood. A vicious circle may be readily formed by the production of venous engorgement of the liver from the absorption of the products of imperfect digestion. Fasting and the use of medicines may break this vicious circle. Dr. Beaumont's observations on Alexis St. Martin proved the close connexion between the tongue and stomach. Stimulation of the gastric mucous membrane by gentle rubbing with a glass rod or feather may cause the same changes in the stomach as the ingestion of food. Pallor and secretion of mucus are caused by strong irritation, and stronger irritation still causes nausea and vomiting. These experiments throw light on the condition known as biliousness. The varying states of the appetite may be explained. Dr. Beaumont observed once in Alexis St. Martin that the tongue had a thin whitish fur when the appetite was craving, the stomach showed several red spots and patches abraded of the mucous coat, tender and irritable; the gastric digestion was prolonged to seven hours. Here there was indigestion. Two days later the usual appetite was gone, the tongue was thinly coated of a yellowish tint, the face was sallow, and the stomach showed several deep-red patches. Mucus and bile were present in the stomach, and coated a muslin bag. The sallowness showed that the condition was one of biliousness, and that the liver was involved. On the succeeding days the venous congestion of the stomach was increased. Persons who suffer from malaria may suffer from disturbance first in the liver and next in the stomach, the opposite to that just described. Malarial poison, whether it be a bacillus or not, appears to have a particular power to affect the liver, spleen, and vaso-motor centres. The usual symptoms of indigestion are flatulence, weight in the epigastrium, acidity, and pain; and it may be worth while to try to ascertain the conditions to which each of these symptoms is due. Analysis of gastric gas shows that it chiefly consists of the gases of the atmosphere from which the oxygen has been absorbed. The gastro-intestinal mucous membrane may secrete gas in large quantities. Malarial patients may suffer from a tendency to flatulence without any other symptom; this being probably due to obstruction of the portal circulation of the liver. Flatulence may be associated with cardiac distress, as in running to catch a train, and as occurs in patients with cardiac disease, as the term "heart-wind" of Dr. Mitchell Bruce indicates. Decomposition of food may give rise to the formation of gas. Gas may pass from the intestines into the stomach. Excessive swallowing of air is regarded by Dr. Brunton as the most frequent cause of gastric flatulence. Tenacious fluids like pea soup carry down a good deal of air. The conditions which give rise to frequent swallowing of air are: (1) Continued salivation; (2) a sense of irritation at the back of the throat; (3) a feeling of acidity in the stomach; and (4) a feeling of oppression about the epigastrium. Irritation of the vagus, as Czermak showed, is the cause of the feeling of constriction across the chest like a huge iron band clutching it, known to the Germans as "beklemmung." Depressing emotions probably act on the vagus nerve centre. Frequent swallowing may overcome the feeling of constriction, since Kronecker showed that swallowing does away with the vagus cardiac inhibition; the popular phrase "swallowed his grief" is related to this. The observations of Ebstein and Zeckendorf[1] seem to show that hysterical distension of the intestines is due to paralysis of the pylorus. An analysis by Kolbe and Ruge of the gases passed per anum by a man after different kinds of food appears to show that it is the production of marsh gas, which chiefly gives rise to the flatulence of the intestines. Marsh gas may be passed in eructations. Ewald[2] had a curious case under his care, in which the patient was astounded to find, on trying to light a cigar, that inflammable gas was issuing from the mouth. Persistent eructations of sulphuretted hydrogen point to serious organic disease.

Acidity and flatulence may alternate in the same individual. The feeling of acidity is not always due to the acid, but

[1] Pathogenese der Bauchtympanie Inaug. Diss. Göttingen, 1883.
[2] C. Anton Ewald, Reichert, Du Bois-Reymond's Archiv, 1874, p. 217.

to an increased sensitiveness of the stomach or œsophagus, or to some abnormal condition of the cardiac orifice. Swallowing a piece of hot potato proves that the œsophagus is more sensitive than the stomach.

Dr. McNaught has shown[3] that in irritative dyspepsia the acidity was not above the normal, and Professor Talma[4] of Utrecht has proved the same thing by giving to patients who suffer from acidity an artificial gastric juice containing only the normal proportion of hydrochloric acid, and yet they suffered from the feeling of acidity. Increased formation of acid by the decomposition of food may cause the feeling of acidity.

The pain of heartburn seems to be due to irritation of the cardia and of the œsophagus, seeing that the pain of the stomach is rather a feeling of weight than of pain. An escape of wind may give relief. It may be that the wind stretches the cardia and so allows the acid contents to come in contact with that structure. Colic may rarely be due to violent spasm of the stomach. Alkaloids absorbed from the rectum into the general circulation produce greater effects, as Mr. Savory showed for strychnia, than when absorbed higher up, probably because the liver has the power of excreting these bodies.

Retarded hepatic circulation, by preventing the too rapid absorption of the peptones, may prove of service to the organism. In his article on diabetes in Reynolds's System of Medicine, Dr. Brunton has insisted on the difference between glycosuria and true diabetes. Lehmann[5] found that sugar injected into the mesenteric veins of a rabbit during digestion does not appear in the urine, although the same quantity injected in the same way in a fasting animal would produce glycosuria.

In some statistics of life insurance drawn up in New York[6] one out of every eleven healthy persons was found to present traces of albumen in the urine. Some experiments by Leube[7] on 119 soldiers showed that in 4 per cent. the morning urine contained albumen, and albuminuria occurred in no less than 16 per cent. after a severe march. Parkes[8] found about 10 per cent. of temporary albuminuria in hospital patients. Dr. Warburton Begbie writes: "It is surely a satisfactory consideration that a condition of excessive albuminuria—the urine becoming nearly solid by heat and nitric acid—may, after all, not indicate the coexistence of any structural change in the kidney."[9] The albuminous substances in the blood appear to consist of such large molecules that they will not diffuse through the healthy glomeruli, but the products of digestion, peptones, and hemi-albumose will diffuse through the glomeruli. The white of egg appears to have a smaller molecule than serum albumen. Dr. Brunton swallowed six eggs in rapid succession, with the result that no albuminuria followed, though a violent headache, with sickness, were produced. Dr. D'Arcy Power, however, succeeded in taking a sufficient number of eggs to cause albuminuria. In this case the digestion was unable to deal with all the egg albumen ingested. The different kinds of albumen may be distinguished by noting the temperature required to cause coagulation. Stokvis proved that hemi-albumose injected under the skin may pass out of the kidneys without producing any injury to these organs, but if the injections be frequently repeated organic disease may be set up. Oxaluria, like albuminuria, may be transient.

According to Esbach, cabbage is singularly free from oxalate of lime, and oxaluria, caused by its ingestion, must be due to some other cause than simple excretion. Esbach[10] points out that if a reducing agent, like sulphuretted hydrogen, be added to a strong solution of urates, crystals of oxalate of lime are at once produced.

Shortness of breath may be due to dyspepsia; this may be mechanical from distension, or it may be due to disturbance of the circulation. Actual asthmatic attacks may occur in relation with disturbed digestion.

The "stomach cough" was next considered. Stomach irritation may supplement irritation of the pharynx, and the combined irritation be sufficient to excite reflex coughing. The pharynx is the place where the respiratory and digestive tracts cross one another, and irritation here may excite coughing and vomiting; this site, too, is readily affected by digestive disorders. Faintness, shortness of breath, and intermittent pulse are signs due to disturbance of the heart from indigestion, produced either mechanically or through the nervous system. Alkaloids may be formed in the intestine and absorbed there, acting like digitalis on the heart. Alkaloids, acting like muscarine, are formed from the decomposition of albuminis outside the body. The microbe of cholera may act by producing alkaloids.[11] What is the cause of sudden death in some gouty patients? It is possible that the contracted kidneys may be unable to excrete a cardiac poison assumed to be formed by disordered digestion in such cases. Some symptoms of indigestion—languor and disability to move—resemble poisoning by curare, and these symptoms may be due to the production of an alkaloid in the intestines.[12] The researches of Ludwig and Schmidt-Mulheim render it probable that peptones are the poisonous agents in such cases. Bocci[13] has found that, from human urine, an alkaloid can be extracted which has exactly the same action as curare. This alkaloid has not been shown to be the same as that obtained by Brieger[14] from the peptones formed by the digestion of fibrin with gastric juice, to which he has given the name of peptotoxin. Bile is not always bitter, though organic alkaloids may be. The absence of bitterness from freshly secreted bile has been observed by Dr. Brunton and Mr. W. E. Green of Sandown; by the latter in a case of biliary fistula. It is conjectured that the bitterness of gall is dependent on admixture with alkaloids. Bence Jones and Dupré have shown that the liver and some other animal organs yield an alkaloid resembling quinine in many of its actions.

The Greeks showed their wisdom by locating hypochondriasis under the ribs and when they made use of the term melancholia. In the "Histoire de ma Vie," George Sand says, "Whether it is the bile which has made me melancholy or the melancholy which has made me bilious—this would resolve a great metaphysical and physiological problem which I will not take up—it is certain that sharp pains in the liver produce symptoms in all those who are subject to them of profound sadness and a wish to die. Since my disease first appeared I have had happy years, and when it seized me again, although I was in the condition most favourable to love of life, I felt myself suddenly seized by a desire for eternal repose." Sydney Smith describes in a very humorous way the connexion between low spirits and dyspepsia.[15] People are fully alive to the liability of poisoning from sewer gas, but they do not perhaps sufficiently bear in mind the danger they are in from the putrefactive products formed in the inside of the body. Senator[16] described a most instructive case in which the patient became collapsed and nearly died with all the symptoms of poisoning by sulphuretted hydrogen generated in his own intestines. Dr. Golding Bird[17] has described a particular class of nervous symptoms in which hypochondriasis and depression of spirits are accompanied by a deposit of oxalate of lime in the urine. Dr. Roberts[18] says, "these symptoms may be present in typical completeness without oxaluria, and conversely, oxaluria may exist in the highest intensity, and even go on to the formation of a mulberry calculus, without causing any of the above-mentioned symptoms." Murchison and Garrod have treated of the irritability due to poisonous substances in the blood.

Headaches are usually due to decayed teeth or irregularity in the eyes; when from the latter the pain is usually occipital or frontal, but it may be temporal. In headache from indigestion the upper surface of the eyeball will be found excessively tender, and the tension in the globe appears to be increased. As the subjects of such headaches grow older the headaches tend to be replaced by giddiness, and this change occurs about the period when the eyes are becoming hypermetropic.

REMARKS ON THE

CIRCULATION OF THE BLOOD.

HISTORICAL NOTICE OF THE DISCOVERY THAT THE VEINS OF THE BAT'S WING, WHICH ARE FURNISHED WITH VALVES, ARE ENDOWED WITH HEART-LIKE RHYTHMICAL CONTRACTILITY, WHEREBY THE BLOOD IS ASSISTED ONWARD IN ITS COURSE TO THE HEART: A PROTEST AGAINST EFFORTS MADE TO IGNORE A CRUCIAL FACT IN NATURE.

BY T. WHARTON JONES, F.R.C.S., F.R.S., &c.

(*Concluded from p. 100.*)

IT would appear that the teaching in respect to the extreme circulation in the bat's wing at King's College has been as imperfect as at University College. At King's College this seems to have been owing to photophobia preventing observation, but at University College there seems to have been, in addition to the spasmodic closure of the eyelids preventing observation, some degree of deafness interfering with the correct acquirement of any knowledge of the subject by word of mouth. If the invalids thus affected had consulted me I would have done my best to relieve them. None, however, came, though I am confident I could have worked a miraculous cure, to the benefit not only of themselves, but also of the students of the respective Colleges. I may, therefore, say of the said invalids, "O! fortunati nimium! sua si bona norint!" Leaving King's College, with its photophobia, I come to address myself to University College. In the "Manual of Physiology" of Dr. Michael Foster, formerly a pupil of University College, now Physiological Secretary of the Royal Society, and Professor of Physiology in the University of Cambridge, of late much in the hands of medical students, and pronounced by the last Harveian orator as being in his estimation the best of its kind, is to be found the following passage (page 155, second edition), where, speaking of alleged rhythmical variations in the "calibre of arteries," he says: "They may be compared with the rhythmic movements of the veins in the bat's wing and of the caudal vein of the eel." This utterance is quite meaningless. If the author had ever observed the objects in nature to which he refers in this manner, he would have ascertained at a glance that, though variations in the calibre of the artery of the rabbit's ear[1] may be seen at frequent intervals (constriction with exclusion of blood and regurgitation, alternating with enlargement by distension with blood, the constriction caused by the action of the tonically contractile muscular fibres of the wall of the artery, while the enlargement by distension with blood is permitted by the relaxation of these same muscular fibres), such alterations are not rhythmical. Again, he would have ascertained at a glance that there are no rhythmical movements of the caudal vein of the eel, either in the form of rhythmical contractions or in that of rhythmical pulsations, though there is a caudal lymph heart, which by its rhythmical contractions propels the lymph into one of the two veins which unite to form the caudal trunk, but that there is no pulsation by rhythmical distension of the vein thereby produced, nor could be under the physical circumstances of the case.[2] And then, again, he would have seen in the bat's wing spread out under the microscope, if he had examined it, phenomena which he would never have described as "rhythmic movements"[3] merely of the veins, without any notice of the course of the blood, as it is thereby influenced. It is, moreover, quite evident that Professor Michael Foster could never even have read in the Philosophical Transactions my paper on the Rhythmical Contractility of the Veins of the Bat's Wing, nor that on the Caudal Heart of the Eel.

Probably what Professor Michael Foster says in the passage above quoted may have been inspired by a jotting in his note book, made when a student attending the lectures of the late Dr. Sharpey, Professor of Physiology in University College and some time Physiological Secretary of the Royal Society. My reason for this conjecture is that Dr. Sharpey's knowledge of the subject in question appears not to have been derived from observation any more than that of Professor Foster. In an edition of Quain's Anatomy, at one time in use among the students of University College, the histological part of which was written by Dr. Sharpey,[4] it is stated that the rhythmically contractile muscular fibres of the walls of the veins in the bat's wing are similar in their microscopical characters to those of ordinary veins, a statement which is directly opposed to the fact.

In my paper in the Philosophical Transactions particular pains are taken to describe, both verbally[5] and pictorially, the peculiar microscopical characters of the rhythmically contractile muscular fibres in question. And by way of contrast I insisted on the fact that the muscular fibres of the walls of the veins of the ear of the long-eared bat which, as above mentioned, are unendowed with rhythmical contractility, do indeed present microscopical characters similar to those of ordinary veins. All this I had long before mentioned to Dr. Sharpey in conversation. Nevertheless, at a meeting of the Royal Society, about fifteen years after the publication of my discovery, having occasion to refer to the microscopical characters of the muscular fibres of the walls of the veins in the bat's wing, I asked Dr. Sharpey, sitting in his chair of office, what grounds he had for stating in a Student's Manual of Anatomy that the microscopical characters of the rhythmically contractile muscular fibres of the walls of the veins in the bat's wing are similar to those of the walls of ordinary veins. To this Dr. Sharpey replied, in a very confident tone, that I had told him so. Whereupon I rejoined that I never told him any such thing. From this it is evident that Dr. Sharpey had not only never examined the objects in nature, and had never read my paper, or even the abstract of it -nay, had failed to hear what I had told him by word of mouth; and yet, *incredibile dictu*, he had for years taught in his lectures what is contrary to the fact in nature, besides recording the same in print.

The business which the founders of the Royal Society proposed to themselves was, among other philosophical inquiries, to discourse of the circulation of the blood, the valves in the veins, the venæ lacteæ, and the lymphatic vessels. Considering that this was the programme of the Royal Society's work two centuries ago, the discovery of the rhythmical actions of the veins of the bat's wing with their valves would then have been hailed with observance, and would have found in Mr. Hooke, the "experimenter," a more intelligent and ingenuous exponent than Dr. Sharpey and his pupil, Dr. Foster, or Dr. Burdon Sanderson, his successor at University College, have proved themselves; while as "curator" Mr. Hooke would have taken better care of the drawings than Mr. Bell did.

Dr. Schiff, the well-known German physiological experimentalist, who at one time carried on his researches in Florence, in a transcendental frame of mind, apparently, interpreted the intermittent constrictions, which the artery of the rabbit's ear may be seen to undergo, as a provision for promoting the onward course of the blood, analogous to that which is found in the systole or rhythmical constrictions of the veins of the bat's wing. The fact, however, is that the effect of the constrictions of the artery is directly the reverse of this. By the constriction of the artery there is produced not only an arrest of the flow of blood, but an actual reflux, the consequence of which is that the ear becomes for the time exsanguine and cold. When, however, relaxation of the muscular wall of the artery supervenes, the flow of blood then takes place freely, the calibre of the vessel being dilated by distension, and the ear becomes again red and warm, as in blushing. All this is so obvious that one is amazed at the blunder. Dr. Schiff, however, did not fail to find proselytes. Dr. Virchow, for example, misled apparently by the current erroneous doctrine that constriction of small arteries sends the blood onward into the capillaries instead of back towards the heart, gave in his adhesion to the opinion.

Some years ago, in a clinical lecture at University College

[1] These must be the variations Dr. Foster refers to. He could surely not mean the less frequent variations in the calibre of other arteries, much less the distensions of arteries constituting the pulse.

[2] This will be shown in another communication.

[3] Here it is to be remarked that no pulsations are caused by the rhythmical contractions of the veins. This, it is obvious, depends on the increasing width of these vessels.

[4] In a subsequent edition by Professor Schaefer I have not found the veins of the bat's wing mentioned at all. A unique kind of muscular fibre not mentioned in a student's manual of histology! This omission is, however, less objectionable than a statement directly opposed to fact.

[5] Verbally also in the abstract above quoted from the Proceedings of the Royal Society.

Hospital, I challenged Professor Virchow to re-examine the point and retract his mistake. I am not aware, however, that he has done so. It is amusing to contemplate how people shut their eyes to nature's work, pretending at the same time that they see things which do not exist—a line of conduct which King Lear sarcastically recommends, thus:

"Get thee glass eyes,
And, like a scurvy politician, seem
To see the things thou dost not."

And all this passes under the name of "experimental research." But it is still more amusing to see how one blunderer improves on the mistake of another. Thus, a former editor of Kirkes' Manual of Physiology, having heard of Schiff's *discovery*, but not taking the trouble to read Schiff's account of it, much less to look on the original, tells his student readers that Schiff had discovered rhythmical contractions of the vein of the rabbit's ear, whereby the flow of blood therein was expedited as in the bat's wing. I called the attention of Mr. Morrant Baker, the present editor of the book, to the blunder, whereupon he struck it out and substituted a true account of what is seen in nature. I here call upon the authors and editors of the text-books on Physiology which I have been criticising to follow the example of Mr. Morrant Baker, and would recommend students to require a demonstration of the real facts in nature instead of the loose assertions made in lectures. They will thereby be saved from the strain and perplexity of mind they undergo in trying to understand what is unintelligible. May I also ask examiners to contribute their assistance in the matter, by inquiring of the candidates whether they have had demonstrated to them such and such facts in nature before asking any questions thereon. On the other hand, it might be suggested to examiners not to propose questions on a subject with the facts of which they have not made themselves acquainted by observations of their own.

To conclude. "Hear now this, O foolish people and without understanding; which have eyes and see not; which have ears and hear not. The prophets prophesy falsely and the priests bear rule by their means; and my people love to have it so."

Ventnor, Isle of Wight.

ANEURYSM OF THE UPPER THIRD OF THE BRACHIAL ARTERY.

LIGATURE OF AXILLARY; HÆMORRHAGE; AMPUTATION AT SHOULDER.

By GEORGE BUCHANAN,
PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF GLASGOW.

SPONTANEOUS aneurysm of the upper part of the brachial artery is very rare. I have consulted the most recent contributions to the subject, and can find only three cases recorded. The most complete and concise account is to be found in the American *Journal of Medical Science* for 1882, in an article by Dr. L. Emmet Holt of New York, to which I refer the reader for details. One case of his own in 1881 was cured by an ingenious instrumental compression. A second case is quoted from the *Buffalo Medical Journal* for 1870, reported by Dr. Kibler, in which the axillary artery was tied in its lower third. Hæmorrhage occurred on the eighth day; the axillary artery was tied higher up, and the patient recovered. The third case was reported by Scarpa in 1809. No operation was attempted, and the patient died of hæmorrhage. A few other cases are recorded, in which the aneurysm was situated at the middle or lower third; for these I refer to the paper above-named and to the recent works on surgery. Cases of traumatic aneurysm have been reported of every part of the brachial artery, in some of which the axillary artery has been tied, but the present paper refers only to spontaneous aneurysm. It is curious that, except Scarpa's case in 1809, no case should be reported till 1870, and the two recorded since have been in America.

The following is a report of what appears to be the fourth case of aneurysm at the upper part of the artery:—

Francis A——, aged thirty-one, a labourer, was admitted on Dec. 3rd, 1884, to the medical wards of the Western Infirmary, under Professor McCall Anderson's care, complaining of numbness and loss of power in the right arm. He stated that about four months ago, without any assignable cause, he felt this sensation for the first time, and that it came on suddenly and continued and increased. About three months ago he found a swelling on his arm beside his armpit, and felt that it was beating, but he had no pain in the spot. On admission he was found to have partial loss of sensation and motion in the right hand and forearm and a continuance of the tingling. The right hand was soft and clammy, and the temperature 94°; while the left was 95·6°. The right radial pulse was almost imperceptible, but that on the left side was full and bounding, as, indeed, was that of every other artery accessible to the finger. The apex beat of the heart was displaced downwards and to the left side. There was a diastolic murmur over the aortic cartilage and a systolic murmur over the aorta. He had a cough and spit, and complained of shortness of breath, and had night-sweats. He admitted that he was habitually intemperate. Dr. Anderson's opinion was that he had a much enlarged heart with aortic disease and some general deterioration of the system owing to his habits of life. The aneurysm being discovered, he was transferred to my surgical wards on Dec. 15th.

The aneurysm was about the size and shape of a hen's egg; the upper end came close up to the axilla and felt very soft, just as if it would give way on the slightest manipulation, but it could be lifted off from the artery, which could be felt beating distinctly in its normal situation just where the axillary ends. When pressure was made with the finger on the third part of the axillary artery pulsation in the tumour completely stopped, but the patient complained bitterly of the pain of the pressure even for a few seconds. The third part of the subclavian could be pressed against the first rib with ease, but the pain was even more severe.

It was quite obvious that there were only two courses open to me, amputation at the shoulder or ligature of the axillary, and I determined to adopt the latter, if there seemed any reasonable hope of success. The two dangers to be feared in ligature of the axillary, even when successfully accomplished without any complications, are gangrene from want of sufficient collateral circulation and hæmorrhage. I was perfectly aware of the anatomical disadvantage of the axillary artery, but I judged that the imperceptibility of the radial pulse proved that the blood was reaching the hand and forearm by some channels which had become established during the existence of the aneurysm. With regard to hæmorrhage, it is true that the vicinity of the great branches of the axillary artery would cause a current which would militate against the formation of a clot above the ligature, and so favour the occurrence of secondary hæmorrhage. But catgut ligature applied with antiseptic precautions acts in a very different way from the ordinary silk ligature, and I hoped, by disturbing the parts as little as possible, to apply a catgut ligature in such a way as to secure consolidation of the wound and included ligature by first intention. If the patient should take chloroform well, if the operation were performed rapidly, and if union by first intention should occur, but little shock would be given to a patient very unable to bear it. On the other hand, amputation at the shoulder-joint in a man enfeebled by excess was a most unpromising alternative.

Accordingly, on Dec. 19th, I ligatured the axillary artery. The patient was put under the influence of chloroform with very great care and anxiety, owing to the known disease of the heart. No inconvenience arose, although he took a large quantity. The arm was stretched out at an obtuse angle to the trunk, and the skin of the axilla thus put on the stretch. The pulsation of the axillary artery could be felt from the upper end of the aneurysm to where it was covered by the anterior fold of the axilla, a space of about two inches. I made an incision about three inches long obliquely across the course of the vessel, and along the lower border of the pectoralis major muscle. After dividing the subcutaneous tissue at the distal end of the wound, I felt the vessel beating directly under the deep fascia, with the median nerve superficial to it. A slight division of this fascia enabled me to put a blunt hook under the nerve, by which it was held aside. A few touches of a director disclosed the artery, the great vein having slipped down out of danger whenever the fascia was divided. Without exposing more of the arterial wall than to allow the introduction of the aneurysm needle, this was passed round and a strong chromic catgut ligature drawn through. It was tied firmly but not too tightly, and the arterial wall proved to be quite elastic and apparently strong. The operation was bloodless, and the wound was

rendered aseptic by the application of carbolic acid solution. The sides were drawn together with four thin silver wire sutures, and carbolised gauze dressing applied. Pulsation was found to be completely arrested in the aneurysm. Cotton-wool was wound round the limb, and the patient was placed in bed with the arm supported on a pillow.—8 P.M.: The patient complains of heat. Temperature 101°; hand and arm quite warm. One-sixth of a grain of morphia given subcutaneously.

Dec. 20th.—9 A.M.: Patient had some sleep, feeling fairly well, but hot. Temperature 99°. No sickness or pain; hand and arm quite warm. I changed the dressing; edges of the wound apparently cohering; no discharge. 8 P.M.: Feels very warm; temperature 103°. Subcutaneous injection of morphia.

21st.—Was restless first part of the night, but after a draught of thirty grains of bromide of potassium quieted and had a good night's rest. Temperature 100°.

22nd.—The patient feels so well that he asked to be allowed to sit up in bed to dinner, but was enjoined the most absolute quiet and rest. I dressed the wound again. To all appearance it was united, with no discharge, but I did not disturb it to ascertain if it were consolidated at the bottom. The aneurysm was much reduced in size, and felt quite solid. Temperature of hand and arm good. At noon the man felt a sudden sensation of pain and called the nurse, who found the bandages soaked with blood. Dr. Somerville, my house-surgeon, was at hand and took off the dressing. He found the wound bulged with clot, but no active bleeding. He obtained the assistance of Mr. Maylard, one of the dispensary staff, who grasped the arm over the wound ready to compress if the flow should recommence. Meanwhile Dr. Somerville telegraphed for me, and by 1 o'clock I arrived at the hospital. The man had been put partially under the influence of chloroform to allow of the pressure on the axilla without pain, and in this state I had him removed to the theatre. On opening the wound and turning over the clots which filled it I found that the blood came with great force from a small opening a short way above the ligature, which was felt by the forefinger to be firmly tied and still grasping the artery. The vessel did not seem to have given way at the ligature, but a short way above it, so that when I pushed the point of my forefinger against the bleeding spot I could easily arrest the flow, and had a small part of the vessel under my finger above the ligature. Keeping my left forefinger on the bleeding spot, with my right hand I split the fascia with a director about an inch further up than at the first operation. The median nerve and musculo-spiral were lying close together on the surface of the artery, but with two blunt hooks they could be easily held apart, and the trunk of the vessel brought into view. The aneurysm needle was passed and a catgut ligature brought round the vessel. This was tied by Mr. Maylard, but was just over the aperture in the artery and failed to check the hæmorrhage. The proceedings were repeated, and this time the ligature was firmly placed half an inch above the bleeding point, and effectually arrested the bleeding. To prevent all risk of hæmorrhage from the lower end of the vessel, I applied, with ease, another catgut ligature between the sac and my first ligature. Antiseptic dressing was then applied as before, and the patient was removed to bed, and ordered to lie absolutely quiet. My house-surgeon watched himself by the bedside till 4 P.M., and thereafter he was watched continuously by my clinical students, who kindly volunteered to take that duty in rotation. At night he was feverish and restless. A quarter of a grain of morphia was given subcutaneously.

23rd.—Passed a good night, and is very easy this morning. Partakes freely of iced milk. In the evening, again, a hypodermic injection of morphia was given.

24th.—Again a good night. Looks much calmer and easier this morning. Dressings not changed. At 1 P.M., when two students were on duty, they noticed blood on the dressings. My house-surgeon was on the spot at once, and, removing the dressing and opening the wound, he placed his thumb on the bleeding vessels and arrested the hæmorrhage. Dr. Beatson, one of the dispensary staff, was sent for, and without delay he took charge of the vessel while the man was put under chloroform. As a further precaution, a door-key, the ring of which was padded with lint, was put over the subclavian. I was summoned by telegraph, and, fortunately, happened to be at home at the time, so that I arrived within twenty minutes of the occurrence. The patient was removed in his bed to the theatre without loss of blood and still under the influence of chloroform. I amputated at the shoulder-joint, making a large semilunar flap above, and completed the operation with very little loss of blood. In two hours after the patient had rallied so as to be able to tell us he was feeling easier, and later on he drank a cup of tea. He slept a good deal during the night, but was restless and feverish from 5 A.M.

26th. At 9 A.M. he was better, but was very feeble; it was obvious he would not completely rally from the shock of the two hæmorrhages and the amputation. He continued in the same state during the day, but became weaker in the evening, and died at 8 A.M. on the 27th.

Anatomical examination of the arm. I am indebted to Dr. Bruce Young, anatomical demonstrator in the University, for a careful dissection of the extremity after its removal. It was quite obvious that the capillary circulation was perfect, with no tendency whatever to gangrene. The vessels were injected with great care from the radial artery; but even though gentle pressure was used, the coats gave way in the middle of its course, and the wax became extravasated, but about the elbow the vessels were well filled. The aneurysmal sac was full of dark clot, very firm, and no doubt in process of complete fibrination. The aneurysm was in the upper third of the artery, just about where the superior profunda is given off, that vessel being found injected adjoining the sac. The whole of the arteries entering the biceps and coraco-brachialis muscles were abnormally large, and one unusual branch, the size of a crowquill, pierced the coraco-brachialis and could be traced running up evidently into the deltoid, where it would inosculate with the anterior circumflex. The whole of the superficial arterioles were unusually enlarged; still it seemed to me strange that when the artery was tied above the superior profunda the blood should pass by these small channels so readily as to secure the limb against even temporary coldness.

Post-mortem examination of the stump.—In the amputation the knife had divided the upper end of the aneurysm, and the aperture of entrance of the artery into the sac was clearly seen. It seemed to have been a fusiform aneurysm, one side of which had become distended into the ovoid shape it subsequently assumed. At the seat of ligature the parts had been matted together, and the relations of the vessels and nerves much altered by the application of the thread ligatures to numerous points at the time of the amputation. The artery from the innominate to the axillary was dissected out from the surrounding parts. It was soft and apparently in the first stage of fatty degeneration, but quite tough enough to bear considerable pulling about. The last ligature which I had applied to the trunk of the vessel on the 22nd was found firmly tied in its place, compressing the sides together, and no appearance of giving way of the coats was to be found. The part of the artery from which the hæmorrhage had occurred on the 22nd had been destroyed in the manipulations necessary to ligature the main vessels at their amputation.

The heart was found to be nearly twice its normal size, the aortic orifice greatly encroached upon by numerous and tough vegetations. The lungs were œdematous. The other organs presented no special features.

Glasgow.

ON FUNCTIONAL AND FALSE MURMURS.

By J. KINGSTON FOWLER, M.A., M.D.,

ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE MIDDLESEX HOSPITAL; ASSISTANT PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION.

(*Concluded from p. 102.*)

5. *Changes in the Pericardium.*—It is quite unnecessary to give the ordinary rules for distinguishing a pericardial friction sound from a valvular murmur. I may, however, point out that these morbid sounds are most frequently heard at one particular spot—viz., the sixth left interspace and over the seventh rib close to the base of the ensiform cartilage. Here the right ventricle is in contact with the chest wall, and it is on its anterior surface that the "white patch" is most commonly found. The sound produced by the movement upon each other of the pericardial surfaces at this spot is systolic in time, usually short, sharp, localised

and superficial; it seldom acquires a blowing character. In fact, it often resembles more nearly a rough reduplication of the first sound than a murmur. It is perhaps doubtful whether the altered sound, which is so commonly heard at this spot, is in all cases due to the presence of a "white patch" on the pericardium. The effect of change of position upon this murmur is variable in some cases. I have found it disappear entirely when the patient is in the recumbent position, as often happens in the case of ordinary friction murmurs audible at other places, whilst at times it is hardly at all affected by such a change. Dr. Angel Money's description of this murmur closely accords with my own experience; it was present in twenty-nine of the 111 cases examined by him. Three years ago I examined a gentleman presenting this murmur, who informed me that, fifteen years previously, his life had been refused for insurance on the ground of valvular disease of the heart.

Another favourite site of these local thickenings of the pericardium is the extreme apex of either ventricle; there it usually appears, post mortem, as a shaggy, villous-looking tuft, covering an area the size of a threepenny-piece, whilst on the anterior surface of the right ventricle it takes the form of an irregular flattened star-like patch.

6. *Altered Conditions of the Muscular Walls of the Heart.*—It has been held that a systolic murmur may be produced simply as the result of the contraction of a hypertrophied left ventricle, but of this I have never been able to satisfy myself, and I am disposed to doubt whether it ever takes place. So far we have been dealing with conditions which suggest valvular disease when it is absent. In the following cases we have to explain the existence of valvular incompetence independent of organic change. The subjects of anæmia, rheumatism, chorea, and, I must add, women in the puerperal state furnish the most common examples of this condition. In such cases it is not uncommon to find a systolic murmur at the apex varying much from time to time in many characteristics, usually soft and blowing, but occasionally loud and harsh in quality; often not limited to the apex, but conducted along the axilla to the angle of the scapula, where it may be distinctly audible. There may be found with it a moderate degree of accentuation of the pulmonary second sound. This murmur indicates that the mitral valve is for the time incompetent, but it does not necessarily imply that any structural change has taken place in it. The exact mode in which this incompetence of the valve is brought about has been, and still is, a much disputed point. The very important researches of Hesse[1] of Leipzig, conducted in the laboratory of Professor Ludwig, have thrown much light upon this and on other points connected with the mechanism of the heart's contractions.

Dr. Hesse by very ingenious means has contrived to obtain casts of the heart and its cavities representing as nearly as possible its exact condition in systole and diastole. From these it appears that, contrary to what has generally been taught, there is no shortening of the left ventricle in systole, that the apex although it moves does not approach the base, and that the distance from the apex to a line through the auriculo-ventricular orifices is the same in systole as in diastole. The conus arteriosus descends slightly towards the apex. The heart becomes cone-shaped during systole and is narrowed at the base in both diameters. The apices of the papillary muscles of the left ventricle approach the aortic orifice, not, however, by any upward motion, but by a movement in a plane parallel with that of the auriculo-ventricular orifices. The result of this movement is to allow the anterior curtain of the mitral valve, which is during diastole stretched obliquely across the cavity, to be floated up so that it may assist in closing the orifice, the musculi papillares at the same time contracting in order to prevent the valves from being driven too far into the auricle. Hesse has also shown what a very important part the contraction of the muscular tissue surrounding the auriculo-ventricular orifices plays in effecting closure of those openings. The average of three observations on different parts showed that the circumference of the base during diastole was 65 centimetres, and during systole 36 centimetres, a mean difference of 29 centimetres; the ratio of the circumference in diastole to that in systole being therefore as 13: 7.2, or a reduction of nearly one-half.

Now, in anæmia the muscular tissue of the ventricles is feeble if it be not in a state of commencing fatty degeneration, the cavities are dilated and the cordæ tendineæ consequently stretched, whilst the auriculo-ventricular orifices are probably enlarged. When systole begins, instead of a reduction in the circumference of the base of nearly one-half there is probably only a feeble contraction, and this, added to the increased initial tension of the tendinous cords, the result of dilatation of the cavity preventing the valves from being immediately floated upward, allows of reflux into the auricle, with the usual result, a systolic murmur at the mitral or tricuspid apex, or at both points of regurgitation occurs on both sides. It is interesting to note that, as in pernicious anæmia, the left ventricle is the first to show signs of fatty degeneration; so in chlorotic anæmia the murmur at the mitral orifice precedes that at the tricuspid. I have lately had under my care two cases, which well illustrate the difficulty that often arises in deciding whether or not a systolic apex murmur is of functional origin or due to organic disease. Both were young girls about eighteen years of age, extremely anæmic, and presenting all the well-known signs and symptoms of that condition. In both a loud systolic murmur was audible at the apex and conducted through the axilla to the angle of the scapula. In neither case was there any evidence of pulmonary engorgement. One patient had suffered from a previous attack of acute rheumatism; in the other there was no rheumatic history. Under the administration of large doses of the carbonate of iron the anæmia in both cases almost disappeared; but, contrary to what one would have expected, a loud apex murmur of undoubted organic origin still remains in the patient who gave no history of rheumatism, whilst in the other case the heart sounds are now quite normal.

In such cases a positive diagnosis can only be arrived at by carefully noting the effects of treatment.

The fugitive murmurs frequently found in the subjects of rheumatism and chorea may, I believe, be best explained on the hypothesis I have used in discussing the origin of the apex murmur of anæmia—viz., regurgitation the result of a feeble contraction of the muscular tissue surrounding the auriculo-ventricular orifices. I confess that I have never been able to understand such a condition as "spasm of the papillary muscles." Hesse's experiments appear to have demonstrated the true function of these portions of the muscular tissue of the ventricles. Time does not allow me to say anything on the origin of the hæmic murmurs audible at the base of the heart; and in the arteries it is a wide and well-worn subject on which I have recently published my views.[2]

Having now reviewed the chief conditions which may produce alterations in the heart's sounds simulating the results of organic disease of the valves, I would venture to suggest some precautions useful in the examination of all cases presenting cardiac murmurs. Assuming that an accurate history of the case has been obtained, which is obviously of the greatest importance, and also that the presence or absence has been noted of those consecutive changes in the heart which are almost invariably associated with disease of any given valve, and of which perhaps none affords more information than the site of the apex beat, if there is still room for doubt, it is well to note carefully the following points:—

1. The exact period in the cardiac cycle occupied by the murmur. False murmurs often do not exactly coincide with the commencement of systole or diastole; they often follow the one and precede the other.

2. The site of maximum intensity and the line of conduction of the murmur, these usually do not coincide with what is found in similar murmurs of organic origin.

3. The condition of the lungs. In doubtful apex murmurs signs of pulmonary engorgement are strongly in favour of organic valve disease, as they are almost invariably absent in the reflux of anæmia.

4. The effect of change of position upon the sound. It is most important to examine every case both standing and in the recumbent position. False murmurs often disappear when the patient lies down, whilst organic murmurs, especially that of mitral stenosis, may be only audible in that position. A murmur which suddenly and completely disappears when the patient lies down, provided there be not at the same time any marked alteration in the pulse-rate, is almost certainly not due to organic disease of a valve.

5. The accentuation of the pulmonary second sound is

[1] Beitrage zur Mechanik der Herzebewegung: Archiv für Anatomie und Physiologie, 1880, p. 328.

[2] On the Origin of Anæmic Murmurs. Churchill. 1884.

much less marked in cases of anæmic than organic mitral reflux.

6. The conduction of an apex murmur to the angle of the left scapula is no absolute sign of organic origin; whilst organic murmurs are often inaudible at that spot.

7. False murmurs often disappear completely when the breath is held.

8. The pulse, which cannot err, may at once negative a suspicion of organic disease founded on the presence of a murmur.

The great importance of an accurate diagnosis in cases of suspected valvular disease of the heart as regards both prognosis and treatment, and the practical difficulties attending it, will, I trust, be considered a sufficient excuse for having brought the rather trite subject before you this evening.

ON

SOME COMPLICATIONS OF TRACHEOTOMY, WITH ILLUSTRATIVE CASES.

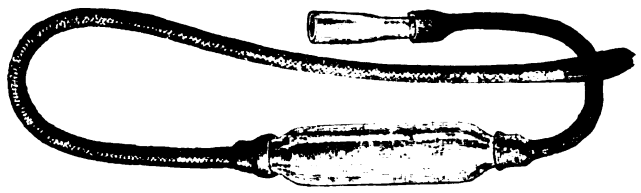
BY ROBERT WILLIAM PARKER, M.R.C.S.,
SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN.

AMONG the cases which present themselves in practice of urgent dyspnœa in children there are some in which a diagnosis is all but impossible; the urgency is so great, the history of its onset so vague and uncertain, that tracheotomy must be performed at once and the diagnosis established afterwards. Amongst such cases will be found a not inconsiderable proportion in which the dyspnœa is not due to diphtheria, but either to a more or less chronic inflammation, or to an unsuspected foreign body or new growth. In many of these cases, owing to the youth of the patient and the smallness of the parts concerned, diagnosis is all but impossible; the true cause may be guessed at but cannot be established, and that being so the proper remedy cannot be applied. I have collected from my case-books of the past eight or ten years a number of these cases, which I purpose relating in the present paper. Their study will help to suggest, in similar cases, a possible diagnosis, and the mode in which sometimes they should and sometimes should not be treated. Cases of diphtheria are a class quite apart; for, besides the local lesion, we have to reckon with a septic condition which may diffuse itself through the system and materially modify the course of the operation. Tracheotomy for removal of a foreign body or for chronic catarrh—a purely local lesion—is an infinitely less serious operation. On the other hand, the subsequent course of these latter cases presents difficulties and anxieties of their own, which are very troublesome. It is chiefly with these that I purpose to deal in this paper, under the term "complications," by which I mean conditions that retard or prevent the restitution of the laryngeal function and the permanent removal of the cannula. These complications are so various and often so unexpected that quite an exceptional interest attaches to them; no two cases ever appear to be quite alike. Some of the complications depend on the almost indispensable use of a cannula to keep the artificial opening in the trachea patent; some depend on the nature of the disease, some on accident.

Certain possible complications connected with the operation itself may just be referred to *en passant*. Occasionally the surgeon, having opened the trachea for laryngeal diphtheria, is disappointed at the non-appearance of air bubbles or mucus or membrane; the truth being that he may have detached a layer of false membrane, or even the mucous membrane itself, from the tracheal wall, and have inserted the tube into the interval so formed. Such a mistake need not lead to any serious consequences, and can be easily remedied; the use of a dilator, and the careful swabbing out of the trachea and larynx, which I advocate as routine practice in all cases of laryngeal diphtheria before any attempt is made to insert the tube, will effectually prevent or remedy such an occurrence. Sometimes, after swabbing out the trachea, when the membrane is very plentiful and very thick, pieces of it get drawn down into a bronchus during forced inspiration, and may materially interfere with the entrance of air into the lungs. Again, if much hæmorrhage occur during the operation, blood may get drawn down into the air passages, where, besides interfering with respiration, it will if left alone shortly decompose, and then give rise to septic pneumonia. In all such cases an effort must be made to remove these obstructions. Other means having failed, the instrument (Fig. 1) will be found very useful.

The death of Dr. Rabbeth, after heroically but ineffectually attempting to suck out membrane and other obstructing products of diphtheria from a tracheotomy tube, induces me to describe this instrument, and the purpose it is intended to serve, more fully than I otherwise should have done, seeing that it is figured and its use indicated in my work on "Tracheotomy in Laryngeal Diphtheria." I hold that diphtheria is largely a local disease at all stages, and that local remedies are necessary if we would successfully combat the disease. With this view I recommend that the larynx and trachea be thoroughly swabbed out with some suitable disinfectant, and that this swabbing be repeated once or twice or oftener during the day, according to the severity of the case, as long as the diphtheritic infection continues to manifest itself by the deposition of membranous exudations. A long feather dipped in glycerine of boracic acid, or other solution, answers admirably for this purpose; its introduction causes the patient to cough, and thus the loosened membrane and other exudations are expelled. Occasionally, however, these exudations get wedged in the bronchi, and then there is more difficulty in getting them out; it is for such cases that my trachea aspirator is intended. Before using, the longer tube is soaked in hot carbolic solution in order to make it supple. The shorter one serves as the mouth-piece. The glass bulb is filled with carbolised cotton-wool; this effectually shuts off the poison from the mouth of the operator when suction is made, for it is well known that even germs cannot penetrate through such a filter as this. The object in performing tracheotomy is not merely the introduction of a silver tube, but the removal of the foreign

FIG. 1.



Trachea aspirator.

matter which has caused the respiratory obstruction, whatever its nature may be, and I believe this may be accomplished through a slit in the trachea held open by a dilator more easily than through a silver tracheotomy cannula. Let the surgeon, therefore, be in no hurry to insert the tube; rather, while the patient is still under chloroform, let him carefully examine the interior of the windpipe, holding it open with a dilator, and make sure that all extraneous matters have been thoroughly got rid of. In one of the cases I am about to relate the diagnosis was difficult and uncertain, but, thanks to this method of dilating the tracheotomy wound and examining the trachea, the true cause of the laryngeal obstruction, a crop of warts on the vocal cords, at once became obvious.

There is a further danger to which I may perhaps just allude, though it is not a complication in the sense in which I am now using the word; I mean the danger of sudden death apart from local conditions. It depends, however, on the fact that the trachea has been interfered with. In my own experience not less than four such cases have occurred. It would seem as if this danger is associated with injury or disease of all the organs supplied by the pneumogastric nerve; thus cases of sudden death are not unfamiliar from simply washing out an empyema cavity, and I can remember a case of gastrostomy in which death rapidly followed the operation, apparently from nerve shock and without other signs to explain it. I will only say that in all these four cases death was quite sudden and quite unlooked for; the breathing appeared to be normal until within a few moments of death, there was no struggling or foaming at the mouth, and that in the cases in which an autopsy was made nothing was found to account for death. The interval between the operation and death varied in all the cases, ranging from four days to four months. I consider them in all respects parallel with the sudden deaths which occasionally follow on opening or washing out

the pleural cavity, or even an over-distension of the pleura. They arise probably from a too powerful or too long-continued irritation of the peripheral branchlets of the pneumogastric.

The cases are classed under the following headings:—1. Acute or subacute changes due to the lesion, for which tracheotomy has been performed. 2. Chronic laryngeal changes. 3. Irritative changes due to the mere presence of a tube. 4. Accidental conditions. 5. Ulceration due to an ill-fitting tube.

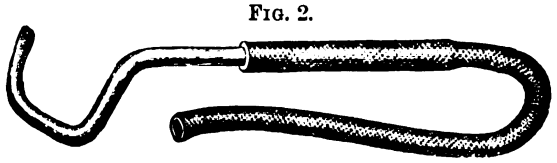
1. *Acute or Subacute Changes due to the Lesion, for which Tracheotomy has been performed.*—In severe cases of diphtheria there is sometimes found deep ulceration with excavation of the mucous membrane after the false membrane has been detached, a condition which may be found at any part of the larynx. Such ulceration is usually accompanied by swelling of the adjacent submucous tissue, and the ulcers themselves not infrequently become covered with florid flabby granulations, which are very troublesome to heal. This thickening of the submucous tissue may also be directly continuous with that in the pharynx, and independent of ulceration. After scalds of the glottis it invariably exists for a longer or shorter period, and in greater or less intensity. It is this swelling that leads to the obstruction to breathing (not seldom fatal) which is known to occur after apparently slight scalds of the pharynx and larynx. At the present time I have under observation a child who was tracheotomised four or five years ago for laryngeal obstruction following a not very severe scald of the glottis. Several attempts to dispense with the tube have been made, but hitherto without success.

In the laryngitis which is occasionally associated with congenital syphilis, the lesion is of a rather different kind; it more resembles the mucous patches which occur in the mouth and about the lips. The membrane is thickened and raised owing to its infiltration with cells; the submucous tissue of course partakes more or less in the change. In older children occasionally a destructive phagedænic ulceration may occur either primarily in the larynx, or by extension from the arches of the palate or epiglottis, or from the wound. In perichondritis such as is met with in a few cases as a sequela of typhoid fever and of other febrile conditions, the inflamed mucous membrane is symptomatic of deeper changes rather than a primary condition; its course, clinical manifestations, and treatment will depend on the primary lesion. A form of laryngitis occurs also occasionally after febrile conditions, and the exanthemata are apparently due to the breaking down of exudative material which has collected in the glandular structures of the mucous membrane. These local conditions, which may all give rise to dyspnœa and necessitate the performance of tracheotomy, will generally persist for some time after the operation; the surgeon is usually brought face to face with his case when the dyspnœa is so urgent that the operation must be performed at once, and the diagnosis made afterwards. It is in such cases that the foregoing conditions become complications, the full significance of which will only become apparent at the end of a few days, when, the urgent dyspnœa having been relieved, the question of removing the cannula begins to present itself. The diagnosis of the various conditions is not very difficult, but it is essential to successful treatment. The ulceration which diphtheria occasionally produces may be suspected in the larynx, if respiration through the glottis is delayed for some time after the general disease has subsided, and more especially if a similar condition has been seen about the tonsils or palate or external wound. The expectoration of bits of membrane or of pellets of inspissated mucus with shreds of necrotic submucous tissue attached and blood-stained on the deeper surface occurs from time to time, and makes such a diagnosis almost certain. In most cases of this kind among younger children there will be considerable delay in laying aside the silver tube; if the child be poor and ill nourished, this ulceration may heal very slowly, and months may pass before the laryngeal function is re-established. In syphilis, a diagnosis which has often to be made by a process of exclusion, improvement will rapidly set in on an antisyphilitic treatment, while the condition will remain stationary or become aggravated if merely treated by general remedies. Apart, however, from this method of diagnosis there may be a history of congenital syphilis, and perhaps also evident syphilitic lesions of other organs: thrush in the mouth, snuffling, condylomata about the anus, local thickenings on the long bones or bones of the skull. Any such signs would be in the highest degree suggestive of the probable nature of the laryngeal lesion, if laryngeal obstruction were found associated with one or other of the above-named conditions. In doubtful cases a mercurial course can be tried if the laryngeal urgency is not very great; a few days at most will suffice to test the value of such treatment.

The action of corrosive fluids and of hot steam or water varies with the amount swallowed, with the nature of the fluid, and with the heat of the water or steam. Occasionally diphtheria, or a membraniform inflammation which is indistinguishable from diphtheria,[1] may attack a throat so injured; in which case treatment will have to be in accordance with general principles, as already laid down. If the laryngeal cartilages become diseased they will have to be removed, and the ulceration of the adjoining mucous membrane will probably not begin to repair until their removal is accomplished; furthermore, the necrosed cartilage may become detached and fall into the air-passages unless it is removed. The history of a case should be carefully ascertained in all instances, not only for purposes of differential diagnosis, but for treatment also. A most troublesome point in many of these cases—one, indeed, common to all—will be the difficulty in removing the tube. A consideration of the history, the probable pathological condition of the larynx and trachea, the stage of the disease, its duration, the age of the patient, the presence or absence of secondary lung complications, are details each one of which will have to be carefully weighed and the treatment varied accordingly.

For the purposes of local applications, whether disinfectant, astringent, or solvent, to the throat, nothing is so effectual as a good spray. I would especially urge the value of a steam spray. The greater power of this over a hand spray ensures a finer pulverisation of the fluid which is being used; and it is thus more easily and more thoroughly brought into contact with every part of the diseased membrane, even up in the posterior nares; it is also more easily tolerated. In cases of diphtheria where solvents are being used to destroy false membrane, a steam spray is of first importance. By causing the patient to inhale through the larynx, or making him attempt to do so, the spray reaches the glottis and materially assists in getting rid of the viscid mucus or membrane which tends to collect at this spot. Occasionally, however, strong solutions of nitrate of silver are required, and these of course cannot be sprayed in. For such cases I have found the little instrument figured above very useful. It can easily be made, and bent to any angle most convenient to the requirements of the case. It consists of a piece of glass tubing bent in the flame of a spirit lamp to the required shape, to the end of which an indiarubber mouthpiece is attached. When about to be used, a little nitrate of silver solution of the required strength is put into it; the pointed extremity is passed through the tracheal wound up to the larynx, and the fluid is blown out through the indiarubber tube. By its use the fluid is brought to bear directly on the part affected.

FIG. 2.



An Instrument for applying Solutions to the Larynx through the opening in the Trachea.

The undetected presence of a foreign body near the glottis is sometimes a source of trouble after an operation which has had to be hurriedly performed, and in which the history of the cause and the mode of onset are not clear. In young children the diagnosis is often very difficult, for a laryngoscope can only seldom be used. Even when the history points to the presence of a foreign body as the probable cause, it is not always possible to detect it. In this respect the following two cases are interesting; I had the opportunity of observing both, but they were not actually under my own care.

CASE 1. *Sudden Dyspnœa; no appreciable Cause: Tracheotomy: Death: Autopsy revealed the presence of a bit of Eggshell in the Larynx.* A small child was taken

[1] For a case of this kind which I have recorded, vide Clinical Society's Transactions, vol. viii., 1875. For a similar case, by Mr. Davies-Colley, see Pathological Transactions, vol. xxxiii., 1882.

suddenly ill with laryngeal symptoms and with urgent inspiratory dyspnœa. It was playing about previously. There was no appreciable cause. When I saw it, shortly afterwards, the child was greatly distressed; its voice was gone, and death seemed imminent. Tracheotomy was at once performed, and gave instant and complete relief. A few days later attempts to remove the tube were commenced, but were quite unsuccessful. The child died in convulsions, and at the autopsy a small piece of eggshell was found adhering to the side of the larynx.

CASE 2. *Sudden Dyspnœa; Fishbone suspected as the Cause; Tracheotomy; Measles; Death; Autopsy; Impaction of Bone in the Glottis.*—A little boy, eighteen months old, taken with sudden dyspnœa while or shortly after eating fish for dinner. The cause was immediately suspected—viz., that he had swallowed a fishbone. A most careful search with the finger was made in the pharynx and upper part of the larynx, as far as possible, but without success. Tracheotomy had to be performed hurriedly. After its completion another search for the suspected bone was made, but with no better success; the tube was then inserted. The boy did well after the operation, except that his temperature remained high. Frequent attempts to remove the tube were made. He could neither phonate nor inspire through the glottis. An attempt to examine with the laryngoscope failed. A catheter could be passed into the mouth through the tracheal wound, but the child continued quite unable to breathe without his silver tube. The question of thyrotomy and other plans of treatment were discussed. The child's age was an element of great difficulty. However, about three weeks after the tracheotomy the child took measles, which was very prevalent at the time, and died of lung complications. At the post-mortem examination the glottis was found quite closed, with a long slender fishbone between the cords. The upper extremity of the bone projected into the pharynx, and it seemed a little remarkable that its presence was not detected by the finger when search was made for it.

These cases are of interest as showing the difficulties which beset diagnosis as well as treatment. In such cases the number of failures will certainly be lessened if the treatment of feathering out the glottis be practised as a matter of routine in all cases. But whether this treatment be adopted or not, it may be laid down almost as a rule of surgery when tracheotomy has been performed on account of a foreign body, that the persistence of the symptoms points to a persistence of the cause; little, therefore, is gained by waiting. The larynx should in all cases be examined, both from the wound and from the mouth, to make sure that the foreign body is not impacted in some part or other of the larynx, and further attempts must be made to remove it.

(To be continued.)

A NEW LONG SPLINT FOR FRACTURE OF THE THIGH.

BY GEORGE SHIRRES, M.B., C.M.,
LATE RESIDENT ASSISTANT-SURGEON, ROYAL INFIRMARY, ABERDEEN.

IT has often occurred to me while putting up cases of fractured femur in Liston's long splint that if the splint could be lengthened after it had been adjusted to the limb, it would be an improvement; and it seemed that such an object might be attained if the splint were constructed of two pieces or slides fitting into one another. That by such means a splint might be made which could be altered to any length so as to suit a child or an adult, and which after it had been adjusted to the limb might be still further lengthened. With these ends in view a splint has been devised of which the accompanying engraving (kindly supplied by Messrs. Arnold and Sons) gives a very good idea. This splint consists of two iron slides freely movable upon one another. The lower slide having its edges inverted so that the upper may fit into it. It is three feet long by three and a quarter inches broad. The upper slide has on its inner surface a strip of iron on each side; these when the slides are fitted into one another form a hollow along which iron plates may move. Each slide has a long narrow slit passing up its centre, on the sides of which supports may be clamped. Each slide is provided with a support; that of the upper slide consists of a brass bar in the form of a screw half an inch long. The top of this screw expands into a flat circular head with a hole in the centre. The foot of the screw passes freely through the centre of a circular iron plate one inch and a quarter in diameter, and is then riveted into the centre of another plate of the same kind. A thumb-screw turning around the brass bar acts on the upper plate, pressing it down. The brass bar passes along the inside of the narrow slit in the upper slide, the edges of the slit passing between the two iron plates which may by means of the thumb-screw be firmly clamped on to it at any part of its length. The lower support is nearly similar in shape to the upper one, and may in the same manner be firmly clamped on to any part of the slit in the lower slide. To the head of this lower support a screw, one quarter of an inch in diameter and nine inches long, is attached; the upper end of this screw passes through the hole in the centre of the head of the upper support. A disc one inch and an eighth in diameter travels along the screw between the two supports and catches the upper one. The thumb-screw of the lower support is provided with a shoulder which passes through the slit in the upper slide when the two slides overlap one another. The lower plate on the upper support and the upper plate on the lower one can be moved along the hollow between the two slides (formed by the two iron strips on the upper slide). So that the splint may be broken at any part by clamping the supports and connecting them by the long screw and disc. By moving the upper slide along the lower and clamping the supports when necessary, the splint may be made long enough to suit any patient, and when the splint has been adjusted to the requisite length it may be still further lengthened by turning the disc on the screw. The upper end of the splint is rounded outwards so as to fit into the axilla, and is provided with holes for the perineal band. There is an aperture in the splint four and a half inches from the lower end to accommodate the external malleolus. There is also a cross-bar fixed to the lower end of the splint acting as a foot-piece, which may be fitted on at either edge of the splint, so that it may be used for either side.

The advantages which I believe this splint to possess are:—It may be set at any length so as to suit a child or an adult. After the splint has been clamped at the requisite length and adjusted to the limb, extension may be put on by simply turning the disc on the screw so as to do away with the necessity of tightening the perineal band, forming at the same time a very easy and practical method of extension. In transport and on board ship, and in circumstances where weights cannot be used, the gradual extension, which can be produced by means of this splint, will, I believe, be found particularly valuable.

In working out this splint I have to thank Professor Ogston, of Aberdeen, for many valuable suggestions. The splint may be had from Messrs. Arnold and Sons, West Smithfield, London.

Tillotson-place, W.C.

CASE OF

VERTEBRO-MENINGEAL RHEUMATISM.

BY J. E. BLOMFIELD, B.A. OXON.,
RADCLIFFE TRAVELLING FELLOW.

THE case of which the following is a short account occurred in the practice of Professor Jaccoud, at the Hôpital de la Pitié, Paris. Taking into consideration its rarity, and the facility with which the diagnosis of rheumatism could be established, it is worthy of wider notoriety than is afforded by being the subject of a clinical lecture, and is certainly interesting as a contribution to our knowledge, which is far from complete, of the various phenomena of rheumatism. The patient was a man of robust appearance, forty years of age, who had enjoyed good general health until the 24th of January of last year, when he presented

himself at the hospital complaining of pain in the region of the neck, of the shoulders, and in both upper extremities. This painful state was not produced by degrees, but had arisen suddenly without assignable cause. The pain was violent, and, according to the description of the patient, it seemed as if his arms were being twisted off. The slightest movement increased the pain. The seat of the pain was not localised, but it seemed to shoot down the arm. The neck was held quite rigid by the contractions of the muscles, so as to prevent any movement of the cervical vertebræ, and this part of the spinal column was bent backwards so as to constitute a slight opisthotonos.

On examining the arm there was nothing seen to account for the pain. There was no redness or swelling, and the joints themselves were quite free from any suspicion of disease; but it was possible to discover that certain areas of the skin were devoid of sensibility; and, further, that these points were spontaneously painful—that is to say, the patient presented the phenomena of *anesthésie douleureuse*. When seen by Professor Jaccoud it was discovered that the region of the spine marked by the fifth, sixth, and seventh cervical vertebræ was very tender. Pressure over this region increased not only the local pain, but also the pain down the arms; and taking into consideration the character of the pain and the local tenderness, the professor came to the conclusion that the lesion was central, and, further, that it was rheumatic, because there was no history of a blow or other injury. There was no evidence of syphilis or tubercle; in fact, he considered it as a case of articular rheumatism of the upper part of the spinal column, involving the meninges; and, in accordance with this opinion, ordered a treatment of sodium salicylate. But to complete this diagnosis there was one point wanting, and that was the temperature. On the day of the examination the patient's temperature was normal, but in the evening it rose to 39·4° C., thus supplying the fact which was missing. The correctness of the diagnosis was well illustrated by the treatment, for the effect of the sodium salicylate was marked and immediate. The pain diminished, and with it the rigidity; and by the end of February the patient left the hospital practically cured, only a slight rigidity of the neck remaining, obviously due not to the muscular contraction, but to the articular lesion. But in the first fortnight of March he presented himself again at the hospital in exactly the same condition as before, with the addition that the lower limbs were also affected in a similar manner. Soon, however, another manifestation showed itself, which is of great importance as adding another item of support to the diagnosis, and that was the tumefaction and redness in the left knee and ankle.

The patient was now a hopeless cripple in bed, not daring to move a limb because of the pain, which, as before, was much exaggerated by any movement, though when encouraged to make the requisite effort it was found that perfect power over the muscles was retained. This, however, did not last long, for towards the end of March it was found that there was a loss of ability to move the limbs however much the patient tried; in fact, there was complete akinesia and anæsthesia of all four extremities. It is an interesting fact that this loss of motion appeared first in the arms and afterwards in the lower limbs. The treatment adopted at this time was iodide of potassium, but no marked benefit was noticed, and the patient continued in much the same state during April, with the exception that defecation and micturition became affected, and the patient passed his motions under him unconsciously.

In the month of May mercurial inunctions night and morning were added to the previous medication, not with the idea of counteracting any syphilitic taint, but because of the well-known property of mercurials of removing plastic deposits, to which his troubles were attributed, and some slight improvement seemed to be gained. In the month of June the patient was again in much the same state, except that an ulcer over the sacrum was added to his other troubles. In September, during the absence of Prof. Jaccoud, the treatment was changed and strychnia was given, and soon after this a sign of improvement appeared, due probably not to the change of drug, but to the salutary influence of time, aided possibly by the previous medication. Whatever was the cause the power of movement began to return, first, in the upper limbs, and then in the lower, and at the same time the anæsthesia disappeared and gave place to a degree of hyperæsthesia, and with these improvements the ulcer on the sacrum began to heal. The muscles were found to have preserved their electric reactions in a normal state, despite the time that they had remained useless.

LONDON HOSPITAL.

TRANSVERSE FRACTURE OF THE PATELLA; ASPIRATION OF THE JOINT; SUPPURATION; ANTISEPTIC INCISIONS INTO THE JOINT, FOLLOWED A FEW DAYS LATER BY WIRING OF THE FRAGMENTS; RECOVERY; REMARKS.

(Under the care of Mr. RIVINGTON.)

FRACTURE of the patella is an injury which requires both care and skill in its treatment, and the fact that there is still so much difference of opinion in the profession as to which is the best method to pursue in such cases is an additional proof of this. The methods employed are numerous, and Mr. Rivington's case was one in which it was necessary to use more than one of these methods, and in which there is every prospect of a strong limb and useful joint being secured to the patient.

Charles A——, aged fifty-eight, was admitted on the 29th December, 1883. He had fractured his left patella transversely a little below the middle, by falling on the kerb. There was a great deal of effusion. A back splint and ice-bag were applied. Two days afterwards the house-surgeon made an attempt to bring the fragments together with strapping. On Jan. 11th, there being still much swelling and effusion, Mr. Rivington aspirated the knee-joint, dipping the trocar and cannula in a strong solution of carbolic acid, and using the spray to make "assurance doubly sure." Only two drachms of mingled blood and serum could be obtained. Antiseptic dressing and an ice-bag were applied. On the 16th the house-surgeon tried to reduce the distance between the fragments with Malgaigne's hooks inserted into strapping and gutta-percha, and the separation was diminished about a third of an inch. This procedure did no good, as it increased the effusion, and the hooks were accordingly removed. A week later, finding that pus was oozing from the puncture made by aspiration, Mr. Rivington had the steam spray turned on and an anæsthetic administered, and he opened the knee-joint freely, making an incision on each side of the patella, removing a good deal of clot from the joint, washing it out, and inserting drainage-tubes. Finding at the end of the week that the case was doing well, he had the patient in the operating theatre, and cut down on the patella by means of a vertical incision in the middle line, removed all the vascular granulation tissue uniting the fragments, scraped the fractured surfaces, taking away projecting edges with cutting pliers, and wired the fragments together. The wire was beaten down on to the patella, the lateral openings enlarged, and drainage-tubes inserted. The operation was performed with all antiseptic precautions, and a back splint applied on its completion. On the 5th the wounds were redressed; there was very little discharge. On the 12th the drainage-tubes were removed, and on the 22nd the openings into the joint had closed. On March 7th antiseptics were discontinued. On the 10th the wounds had healed. On the 22nd the limb was taken off the splint. There was considerable inflammatory thickening round the knee-joint, and it was slightly painful as well as stiff. On the 25th the patient was allowed to get up. Change from the horizontal to the vertical position produced œdema of the limb. The patient, naturally a spare, delicate-looking man, was in fairly good health, although weakened by his long illness. He could not bear any weight on the limb. By April 7th he was able to walk a little, but his feet swelled when he was up, and more especially the left foot. He was ordered an elastic bandage. He had very little movement in the joint, and no attempt was made to remove the stiffness for fear of breaking down the union of the fragments,

as has happened in other cases. The knee-joint ached occasionally, but there was no severe pain. There was bony union, and the patient was daily gaining power when discharged.

Remarks by Mr. RIVINGTON. Although it may not be desirable to treat all cases of fracture of the patella by wiring, and although I should hesitate to undertake the operation in an old case where there was much separation, and where division of the quadriceps was likely to be required to bring the fragments into position, I think the procedure is indicated in recent cases like the foregoing, where there is difficulty in drawing the fragments into good position. Hitherto the operation, considering that it is a new procedure, has been attended with very favourable results, for though two deaths have taken place in more than fifty cases, in one at least of the cases certain precautions were omitted which experience would now suggest. There was no lateral incision made for drainage, and the fragments were not brought nearly into apposition. When this is found to be impracticable it would be safer to abandon the operation, as I think was wisely done by my colleague, Mr. Mansell Moullin, in his published case. In the second fatal case the operation was severe, and the patient, being a hard drinker, was a most unfavourable subject for its performance. The failure of the aspiration in the present case was doubtless due to the late period of its use, the blood having coagulated in the joint, and I think the suppuration must be attributed to the attempt made to bring the fragments together with Malgaigne's hooks. I should not myself have selected this procedure whilst the effusion remained unabsorbed. The use of Malgaigne's hooks I have always avoided, except when employed by insertion into strapping or gutta-percha. Some years ago a case occurred in which the direct use of the hooks necessitated amputation of the limb. On the other hand, some very good results have followed their employment in the mediate method mentioned. Two cases in which bony union and good movement were obtained were shown at the London Hospital Medical Society about a year ago. They had been under my colleague, Mr. Couper. I examined them carefully, and could not detect any mobility of the fragments, which were apparently united by bone. Time, however, sometimes proves the fallacy of supposed bony union. In a lecture published by Mr. Hutchinson in March, 1882, he states that he obtained bony union in about half his cases treated with back splint, strapping, ice, and abstinence from examination of the fragments. I have not myself been able to obtain anything like this proportion of osseous union by the same method, and I must confess that I am sceptical as to the proportion given even by so deservedly high an authority. The future treatment of fracture of the patella must, I think, depend on whether bony union is to be obtained. If possible or not, certainly limbs do not always appear to be so useful or satisfactory to the patients when bony union has been secured as in many cases of fibrous union; but, on the other hand, there are a good many instances of fibrous union in which life is rendered miserable by the condition of the limb. If we are to be satisfied with fibrous union, Mr. Heath's plan of immediate treatment by plaster-of-Paris, allowing the patient to walk about on crutches, is as good as any other, and obviates the risk of atrophy of the quadriceps and the disagreeable confinement to bed. If we are to aim at bony union, some other method more reliable than the ordinary modes of treatment must be adopted. In Mr. Mitchell Banks's valuable Clinical Notes mention is made of a simple plan of bringing the fragments together by passing a thick silver wire through the joint immediately underneath the patella, and pressing the fragments together and retaining them in apposition by twisting the ends of the wire over pads placed in front of the bone. Antiseptic precautions are adopted. I have not yet had an opportunity of trying this method, but I hear it favourably spoken of by those who have done so. The interval in the above case, between opening the joint to remove breaking-down blood-clot and wiring the patella, was allowed to elapse for the purpose of avoiding any discredit to the operation in case the foundation had already been laid for inflammatory action and blood contamination by the breaking down of the wound made in aspiration. The patient's temperature had risen to 101°, and he did not seem so well as he had been. He improved after the joint was cleared, and his temperature did not exceed 99° during the treatment after wiring the patella.

BOURNEMOUTH COTTAGE HOSPITAL.

SEQUEL TO THE CASE OF BULLET WOUND OF THE SKULL; NECROPSY; REMARKS.

OUR readers will recollect the case of bullet wound of the skull which was published in THE LANCET of Jan. 10th, and will read with interest the following notes of the case, for which we are also indebted to Mr. F. Gardner, who appends remarks. The patient was under the care of Dr. Hartford during the latter part of the time. Cases of injury to the brain are not uncommon. Bullet wounds are somewhat infrequent in civil practice; when they do occur, they are usually the result of attempted suicide, and a fatal result generally ensues early. At the present time, when the surgery of the brain has received a fresh impetus, tumours being not only diagnosed and localised by the physician, but removed by the surgeon, the careful observation and record of cases of wound or injury of that organ are specially important.

The patient remained quite well from Dec. 13th until Jan. 1st, 1885. The wound did not heal, however, a small quantity of pus escaping daily.

Jan. 1st.—The patient complained of much pain in the head. He had had no sleep. There was very little discharge from the wound; there was no paralysis; no fever; pulse 60.

2nd.—Pain in head had increased; patient was more restless. There was an increase in amount of discharge from the wound. He complained of loss of vision of both eyes. Temperature 97°; pulse 40, and weaker.

7th.—Vomiting came on and patient was more restless; bowels constipated.

9th.—Patient had constant nausea, also a convulsion. Temperature 97°; pulse only 20. Breathing was very slow and there was considerable accumulation of mucus in the throat and chest. Bowels constipated in spite of purgatives. Patient was only semi-conscious.

11th.—Patient became more and more comatose, and died at 4 P.M.

Autopsy, twenty-three hours after death.—Rigor mortis well marked; body well nourished. The wound in the left eyebrow presented the appearance of a depressed cicatrix, the centre being adherent to the structure beneath. A small sinus passed in some distance to some rough bone. On opening the skull the membranes presented no sign of recent or old inflammation. On removing the dura mater the surface of the brain presented a healthy appearance, except at the anterior aspect of the left frontal lobe, which was blackened, and from which a quantity of very fetid green-coloured pus escaped through an opening inadvertently made into the substance of the brain in removing the calvaria. On removing the brain the cranial nerves were seen to be healthy, and the dura mater lining the base of the skull showed no trace of inflammation. The neighbourhood of the wound in the frontal bone was next examined. A mass of bone projected on the inner surface, the mass presenting sharp bony points, to which the brain was firmly adherent. This mass of bone appeared to have been pushed through the dura mater, and so pressed directly on the brain at a spot corresponding to the blackened surface of the left frontal lobe. Some loose pieces of bone, with rough edges, were removed from the inner and upper aspect of this projecting mass. When removed, a cavity was opened, in which lay the bullet flattened antero-posteriorly and separated from the skin and depressed cicatrix in the wound by small pieces of bone similar to those removed from the inner part of the projecting mass. The bullet lay immediately beneath the level of the outer wound, resting on the orbital plate of the frontal bone. The cavity in which it rested had blackened walls and contained a little pus. The brain was then examined. The whole of the left frontal lobe was blackened on its anterior aspect, and its substance was occupied by a large abscess containing some three or four ounces of very offensive-smelling, greenish-coloured pus. The smell was characteristically gangrenous. The rest of the brain was healthy; there were no signs of inflammation or other collections of pus. The other viscera were not examined.

Remarks by Mr. GARDNER.—The post-mortem examination confirms the opinion given that the bullet in this case remained within the skull, although the patient to all intents and purposes recovered from the injury. The man was shot on Aug. 13th, 1884, and was discharged from hospital on Oct. 1st, 1884, strong and well, with only a small granulating wound at the seat of injury. He remained quite well

without a single symptom, cerebral or otherwise, until Jan. 1st, 1885, three months after he left the hospital. The wound, however, had never healed. On Jan. 1st, 1885, he first complained of headache, and after twelve days he died. This case makes another addition to those already on record of the possibility of recovery even with a foreign body within the skull, and in close proximity to the brain. Such cases are now not very rare. The points of rarity in this case are:—1. The absence of meningeal inflammation, although the dura mater was pierced by a mass of bone with rough edges. 2. The absence of cerebral symptoms, although this mass pressed upon the brain and its sharp bony points were adherent to the brain substance. 3. The absence of any fever during the last twelve days of life, although post mortem an abscess containing four ounces of fetid pus was found in the frontal lobe of the brain surrounded by gangrenous brain substance. It is also worthy of note that in the remarks on the case as published in THE LANCET of Jan. 10th, the probable situation of the bullet was suggested as being below the level of the wound and resting on the orbital plate of the frontal bone. In this position it was found and, as also proposed, the brain was uninjured by the ball itself. That such an accumulation of pus should be found within the brain with no symptom of fever, paralysis, or cerebral irritation, beyond headache, is a remarkable fact.

HALIFAX UNION INFIRMARY.

A CASE OF CÆSAREAN SECTION; DEATH; AUTOPSY.

ON Dec. 30th, 1884, Dr. Dolan performed the operation of Cæsarean section on a primipara, aged twenty-six, a pianist, whose height was only 3 feet 11 inches. She had been in labour five hours. There was great pelvic deformity, the antero-posterior diameter being one inch and a half. Carbolised catgut was used for the uterine wound, silver wire for the abdominal walls. The child was living. The patient died in fifty-four hours.

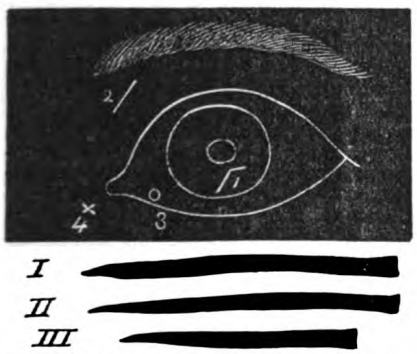
A post-mortem examination was held seventeen hours after death. The uterine wound was found open, a large clot having been forced through it, owing to the occurrence of vomiting. There was peritonitis, which was the probable cause of death.

NEWCASTLE-ON-TYNE INFIRMARY.

WOUND OF THE CORNEA, WITH PROLAPSE OF THE IRIS; REMOVAL OF FOREIGN BODIES FROM THE ORBIT; CURE.

(Under the care of Mr. FREDERICK PAGE.)

THREE months ago a young married woman was admitted into the Newcastle-on-Tyne Infirmary in consequence of an injury to her left eye, which she had received three days previously, as she said, from a blow. Both eyelids were swollen, and in the cornea, at the situation indicated on the diagram 1, was a ragged wound, a quarter of an inch in



length, through which a piece of iris protruded the size of a large shot. There was no blood in the anterior chamber and the lens was unaffected. No other wound could be seen. A strong solution of atropine was put into the eye at intervals, and twice or thrice the protruded iris was touched with nitrate of silver. In a few weeks the wound in the cornea healed, and she was allowed to go home, still, however, with some swelling of the lids. Six weeks after the accident she returned complaining of pain and difficulty in opening her left eye. At the situation marked 3 in the diagram a foreign body could be felt beneath the skin some distance from the surface. The lid could not be everted. A cut was made in the skin, and with some difficulty a steel headless nail, of which I. is an exact outline, was extracted from the orbit. In a few days she was seen again, and in precisely the same situation another foreign body was detected. She was put under chloroform a second time and another nail (II.) extracted. On everting the lid an unhealed wound in the palpebral conjunctiva was seen, through which the nails had entered the orbit. Eight weeks after the accident she again applied, complaining of a purulent discharge and uneasiness about the inner canthus. At the spot marked 4 another nail could be felt through the skin. Separating the lids as far asunder as possible with a speculum, under chloroform, a careful search showed an unhealed wound of the conjunctiva of the lower lid, from which another nail (III.) was drawn out of the orbit. In the sclerotic, opposite this wound, and in a line with the wound in the cornea, was the cicatrix of a recently healed puncture; and Mr. F. Page believes that nail III. had transfixed the globe, entering at the ragged wound in the cornea, passing out of the eyeball at the spot marked 2, and burying itself in the orbit at 4. The patient now has a useful eye, her sight is unaffected, and her pupil nearly perfect.

On going more carefully into the history of the case it was ascertained that the woman was in a cupboard reaching an iron saucepan from a shelf above her head. The saucepan fell, struck her on the head, and she fell down insensible. In falling, to reach the floor she had to pass another shelf, upon which stood a flat box containing a number of nails like those taken from the orbit. It is strange how these nails got where they were found, and passing strange that the patient should have escaped without injury to the optic nerve or brain, and with a good useful eye. It may be added that the patient is a strong healthy woman with a family, and that there is no reason to doubt the account she has given of the accident.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Conclusion of the Discussion on the Tubercle Bacillus and Pathology of Phthisis.

A SPECIAL meeting of this Society was held on Wednesday last, the President, Dr. George Johnson, F.R.S., in the chair.

Dr. K. FOWLER said that he wished to make a few remarks on the distribution of the lesions of phthisis, more especially in relation to the presence of some septic virus as the agent in disseminating tubercle from one part of the lung to another. Tubercular lesions were not found to extend at random through the lungs, and generally not by direct extension of the morbid process. The situation of the secondary lesions of phthisis gives evidence of the presence of tubercular virus. It should be observed that lesions in the upper lobe do not differ from those found in the lower lobe; those who hold to the inflammatory theory say that the tubercular disease is grafted on the primary inflammation. He was frequently seeing cases of arrested phthisis; such instances were met with clinically and at the post-mortem examinations. In those who die of cancer evidence may be found that they had previously been the subject of tuberculosis; there is a family history of phthisis in many cases of cancer. In the specimens of arrested phthisis some puckering of the pleura and fibrosis of the underlying lung, with pigmentation, were to be found; and very frequently also there was infiltration about the posterior horizontal branch of the bronchus, near to the posterior apex of the lower lobe, and almost exactly opposite the fifth dorsal spine. This lesion may be arrested in the state of cavity. In other cases of phthisis this region was very prone to be affected. He considered that the virus of phthisis was of a specific nature, and since the bacillus had been discovered he was inclined to accept it as the specific agent. This virus would account for the auto-infective property of tubercle. The secondary deposit of tubercle was not always situate on the same side of the lungs as the primary one; we may have a "crossed lesion," and in these cases the patient could not lie on the side the lung of which was primarily affected. Probably infection took place during the night, and was due to the

inhalation of septic material along the bronchi. He believed in the unity of phthisis. With regard to heredity, he could not concur in the views of Germain Sée, that the child derived its tubercle from the blood of the mother during fœtal life. In most cases of acquired phthisis he thought that the virus of the disease was taken in through the respiratory passages. There was danger from the close aggregation of healthy with tubercular individuals when a predisposition existed in the former; predisposition may vary at different periods of life, just as may be evidenced in zymotic diseases. Three factors were necessary to the development of tubercle: (1) the seed of the disease, which was probably the bacillus; (2) a proper soil, either hereditary or acquired; and (3) certain conditions, which may vary from time to time even in the life history of the individual.

Dr. S. Coupland spoke of the great contrast between the views now prevalent and those generally held about 1873, when the discussion took place at the Pathological Society, at which Dr. Wilson Fox and one or two others were the only supporters of the view that all phthisis was essentially one and the same disease. He considered that whereas Dr. Bastian advised at that meeting the absolute disuse of so misleading a term as tubercle, it would appear that now the word would be quite appropriate. Our conception of tubercle is now infinitely wider than when Virchow first gave the name to the miliary bodies. Whereas histological features were generally accepted as the test for tubercle, and experimental inoculations used to be thought fallacious, now the position was reversed, and histology was regarded as insufficient to establish the nature of a supposed tubercle. The views which regarded phthisis as everywhere the same were more firmly substantiated by the recent additions to knowledge, and these recent acquirements were decidedly of value even if they only confirmed the knowledge which had already been attained. If we apply this new test of the bacillus to discriminate the tubercular from other lesions, the field of tubercular disease will be found to be very much widened. Koch had found the tubercle bacilli in two cases of ulcer of the tongue, in four cases of strumous pyelitis, in cases of chronic disease of the bladder and rectum and of suprarenal disease, and in a case of tubercular disease of the uterus; also in specimens of strumous disease of the testicle, and in caseous tumours of the brain, as well as in twenty-one strumous caseating lymphatic glands, chiefly of the neck. The bacillus had been found also in the granulation tissue of chronic disease of joints and of diseases of bone, and scantily in examples of lupus of the skin. These observations are quite in accordance with the accepted views of tuberculosis as a general infective disease which may attack the body at any point, and which thence is liable to become further disseminated throughout the system. The evidence in favour of the real arrest of the tubercular process was strong. It might be that it was through the activity of the bacilli that the caseous matter is softened, and hence an explanation of the large numbers of bacilli usually found in caseous matter is afforded. It might be that, owing to the inertia and want of activity of bacilli, parts became shrivelled, fibrous, and cretified.

Dr. Theodore Acland said that it required one who had worked in this field to properly appreciate the value and labour which Dr. Kidd had bestowed on his researches. He proposed to deal only with the practical side of the question, and proceeded to relate the results of some observations made by himself and Mr. Edmunds on the presence or absence of bacilli in the sputum. In all cases where it was possible he had inquired into the occurrence of the bacilli in the tissues of the patient after death. He had succeeded in finding bacilli in nearly all cases of tubercular disease which he had investigated. In some instances he had found innumerable bacilli during life, but none after death. In others, though there were innumerable bacilli found in the lesions after death, he had not detected any during life. Special mention was made of a case of laryngeal disease in which, though bacilli were abundant, there was not a single giant cell to be seen in the tubercular lesion, though many microscopic sections had been examined. In three cases of general tuberculosis he had not been able to discover a single bacillus; also in one of tubercular peritonitis, and in cases of tubercular disease of joint and bone. He had not found the micro-organisms in those tissues which had not been exposed to the atmosphere. His methods might have been at fault, but yet in every specimen of Perlsucht in bovine tuberculosis he had not failed to detect the bacilli. He alluded to the fact that Dr. Hensen of Bergen had found bacilli like those of tubercle in leprosy and glanders. He asked how it was that there was frequently no proportion between the number of bacilli and the extent of the tubercular lesion. Reference was made to a paper recently read by Mr. Croft, in which, though many specimens of diseases of the joint were examined, he had not been able to procure a single one in which a bacillus was present; and, further, Dr. Mules had been unable to discover bacilli in tubercular choroiditis (Ophthalmological Transactions, 1884). Here we must suppose either that the lesions were not tubercular or else that bacilli may be absent.

Dr. Douglas Powell then read a letter from Dr. Creighton, which expressed regret that he was unable to be present at the meeting. The chief passage in the letter was as follows:—"The interpretation put by Mr. Watson Cheyne upon a printed sentence of mine relating to Koch's procedure is one that I certainly did not intend it to bear, and did not suspect that it could be made to bear. I wish most explicitly to disclaim any charge of personal bad faith against Dr. Koch, and to express my regret that the words 'his omission might be taken in good faith,' which I inadvertently let pass, should have given the slightest colour to that charge."

Dr. Heron congratulated Dr. Kidd on so valuable a piece of work, which was an able endorsement of the work published by Koch in 1882. He then criticised some of the remarks made by Sir Andrew Clark, who stated that in eleven cases of fibroid phthisis he had not discovered the bacillus, though whether the investigation was clinical or anatomical, or both, did not appear. The bacillus would most certainly be found in such cases if sufficient search were made. Similarly with regard to the cases of acute tuberculosis in which no bacilli had been detected. He considered, in opposition to Sir Andrew, that if the life history of caseous pneumonia were so very distinct from the life history of tubercular phthisis, the occurrence of the same bacilli in both forms of disease tended to minimise the importance of the part played by the life history. At the London Hospital, a few years ago, he ventured to assert that the presence of the organism might be an aid in prognosis, for where the bacilli were numerous he predicted a rapid course, and where they were scanty a slow one. He was glad to hear the remarks of Dr. Moxon on the prognostic significance of clumps of bacilli in the stained specimens of sputa, for he had also made the same observation, and seeing that it remained so long unverified, he had been somewhat disappointed.

Dr. Bernard O'Connor criticised some of the remarks made by Dr. Green and Mr. Watson Cheyne. If bacilli were the index of tubercle, what are we to say about Lustgarten's discovery, in chancres and syphilitic gummata, of bacilli undistinguishable from the bacilli of tubercle.

Dr. Drysdale reviewed the various theories which had been extant during the past forty years. After studying at Paris and working at the Consumption Hospital, he became convinced that phthisis was a virulent inoculable disease. He said that the bacilli had now been discovered in about 3400 cases and were absent in but a few. He regarded this new doctrine as the most important addition to pathology known to him.

Mr. Macnamara referred especially to the investigation of early stages of tubercular disease of bone, such as may be met with in the head of the femur, where the child not unfrequently dies from tubercular meningitis or from tubercle of the lung. He had failed to verify the presence of tubercle bacilli in a growth which could be nothing else than tubercle. The process began at the junction of the diaphysis with the epiphysis. In five or six cases most thoroughly examined, he had never been able to discover the bacillus in the early stage of the disease, though he had frequently found the micro-organisms when a sinus communicating with the open air led down to the diseased bone. Reference was made to a case, in which the patient had suffered from pain in the femur for years, which had been under the care of Mr. Cowell. In this case a sudden accession of fever with formation of abscesses in the popliteal space was the indication for amputating the limb. It was then found that the matter was full of bacilli, although there had been no external opening, and without there being any opening into the cavity of the bone itself. The bone was exhibited to the Society. This patient had no symptoms of phthisis, and it was surprising that there should have been no extension to the rest of the body.

Dr. Percy Kidd, in reply, said that the discussion had

not called in question the specificity of the bacillus until this evening. Remembering the ignominious collapse which took place after Spina's publication, it would be well to hold our hands before accepting the results of Lustgarten's researches in syphilis. The objections made by Dr. Creighton, if they could be sustained, were serious; but it seemed to him that Mr. Watson Cheyne had already fully answered them. Dr. Wilson Fox had referred to the aniline dyes as liable to lead to error, but Koch did not trust solely to the staining of the bacillus as a means of proving his point, for the cultivations and inoculations were far more important, though the staining was a convenient method of finding the bacilli in the tissues. Koch admitted that other micro-organisms may give similar reactions—as, for example, that of leprosy. With regard to Dr. Green's definition of phthisis, he would accept it as more perfect if the qualification that "consolidation which had a tendency to undergo fibro-caseous changes" were added. The idea of the septic virus had been known since the time of Villemin. He agreed with the views of Dr. Wilson Fox and others on the unity of phthisis. In his own experience he had found the detection of the tubercle bacillus to be of great value in doubtful cases. It must have been a great satisfaction to Dr. H. Weber to have predicted that phthisis was a germ disease so long ago as 1868. From his observations he would say it was not uncommon to find the bacilli *in* the ordinary cells of tubercle, especially in cases of acute miliary tuberculosis. With regard to the observation of Metschinkoff, quoted by Mr. Sutton, he thought that it was of much significance. The insemination of tubercle might be prevented by the protective influence afforded by the vigour of the cells of those individuals who were not prone to phthisis. He regarded the epithelioid cells of tubercle as perhaps the most important histological elements in the early lesions of tuberculosis. As to the remarks of Dr. T. Williams on the protective action of the giant cells, he said that this was not proved by the bacilli being at the periphery of the cell, for it was here that the nuclei were situate, and where activity was greatest. The giant cells seemed to be inert structures, and in his opinion did not have any defensive action. The small number of bacilli in acute miliary tubercle was remarkable; the bacilli were more numerous in nodules rather larger than the miliary bodies, and where there were the signs of catarrhal pneumonia round about them. The number of the bacilli probably depended on the stage of growth. It was not at all infrequent to have to examine many sections before bacilli were found. As to the method of preparation and examination which he had adopted, he could only say that he had followed the account of Mr. Watson Cheyne, given in the *Practitioner*, in his report to the British Medical Association. The sections were left about twelve hours in the first staining solution, though two hours, with sufficient warming and changing of the fluid, were enough in some cases which he had tried. He advised the use of benzol instead of chloroform for dissolving the Canada balsam, and cedar oil instead of oil of cloves. At one time he believed the bacilli were only to be found in lesions exposed to the atmosphere, but he had now given up this notion. He had undoubtedly seen bacilli in a caseous vesicula seminalis, though they were rather scanty. In this patient there were follicular ulcers in the ileum. It is possible that the spores of bacilli may be present without the rods; and as the former may not be stained by the ordinary methods, this would explain the failure to find bacilli in some cases. Inoculation was followed by tuberculosis, even when the tubercle failed to yield evidence of bacilli. Koch had found bacilli in every one of nineteen cases of acute miliary tuberculosis examined, and Dr. Kidd had not failed to discover them in six instances. He regarded Mr. Watson Cheyne's suggestion of a chemical poison produced by bacilli as very valuable. He believed that spread by contiguity only took place to a small extent; the blood-vessels disseminated tubercle widely. Bacilli may be seen reaching into the lumen of the artery in tuberculosis of the pia mater. Weigert's observations on the spread of tubercle by the pulmonary veins were made before the bacilli were discovered. He could not coincide with the views of Dr. Moxon, that we should not expect to find tubercular bacilli in cases of fibroid phthisis. In conclusion, he did not think that the bacillus afforded a complete solution of the tubercular process, though he believed it to be essential. Koch had suggested abrasions on the skin as not improbably the mode of inoculation in some cases. The desquamation of epithelium after measles was a doubtful explanation of the determination of tubercle to the lung. It was not impossible to explain the wide differences between caseous pneumonia and fibroid phthisis on the views now held. As to diathesis or disposition, he asserted that some peculiar disposition on the part of the individual was necessary. There was nothing to support M. Germain Sée's notion of the mode of inheritance of tubercle. He was in complete accordance with the views of Dr. Andrew, expressed in the Lumleian Lectures, which postulated the coexistence of a predisposition with the introduction of some virus from without.

PATHOLOGICAL SOCIETY OF LONDON.

Malignant Disease of the Spermatic Cord. — Congenital Disease of the Heart.—Synostosis of Dorsal Vertebræ.—Tubular Epithelioma of Upper Jaw.—Suppuration in Joints in Congenital Syphilis.

AT the ordinary meeting of this Society, held on Tuesday last, Dr. J. Syer Bristowe, F.R.S., President, took the chair for the first time.

Dr. BRISTOWE, on taking his seat as President, delivered an address, in which he glanced at certain points in the history of the Society as he was acquainted with it from personal experience, and recalled certain reminiscences of some of its presidents in its earlier years—of Dr. Latham, Mr. Cæsar Hawkins, Dr. Babington, and Dr. Copeland. The Society had only been in existence a few years when Dr. Bristowe joined it, and he bore witness to the success which it more rapidly attained than any other Medical Society; it became and continued a success because it satisfied a real want. It was emphatically the Society of the young and ardent seekers after truth in that branch of knowledge which is the foundation of all scientific medicine. The Society could only encourage original investigation of the first order indirectly by inducing workers to display specimens which presented points of novelty or of special interest. Its chief duty was the collection and record of material; discussion of the specimens shown could never be prolonged, for it was impossible for anyone to discuss an abstruse pathological subject on the spur of the moment. He fully agreed with the view expressed by his predecessor in the presidential chair, that the formal debates which had been held on several occasions lacked spontaneity, and were in reality but a series of monologues.

Dr. PYE-SMITH, at the end of the meeting, proposed, in a few well-chosen terms, a vote of thanks to the President for his address, which was seconded by Dr. CAYLEY and carried by acclamation.

Mr. A. J. PEPPER read notes of a case of Myxoma of the Left Spermatic Cord, removed from a patient aged seventy-five years. The tumour had been growing for ten months; it weighed, when fresh, rather more than a pound. It was completely encapsuled and was readily shelled out of its bed of areolar tissue. Two or three small cysts projected from the growth, the anterior surface of which was deeply grooved by the spermatic cord. Neither the testicle nor the vas deferens was implicated. There were no secondary deposits. The sectional surface presented generally a gelatinous quivering appearance. Under the microscope there was seen a clear ground substance, threaded by fibres of connective tissue, and strewn with round, oval, angular, and branched cells. In some parts round and fusiform cells, and even cartilage cells, were to be seen. The author of the paper remarked that he had used the term "malignant" on account of the rate of the growth of the tumour and its structural affinity to sarcoma. He then alluded to several recorded cases of connective tissue tumours springing from the spermatic cord, and remarked on the impropiety of classing them with the carcinomata, since in the first instance they attacked neither the skin nor the spermatic epithelial tract.

Mr. PEPPER also exhibited specimens of Colloid Cancer. The primary growth sprang from the connective tissue of the left spermatic cord, apparently having arisen from the remains of some fœtal epithelial structure, since neither the testicle nor the vas deferens was affected. Seven years later the œsophagus became the seat of colloid cancer, and from this the patient died. At the post-mortem examination similar deposits were found in the omentum, abdominal glands, and in the right spermatic cord. Dr. BRISTOWE inquired whether the disease was colloid in the œsophagus; this was answered in the affirmative.—Mr. ALBAN DORAN

asked whether there were secondary growths within the cyst of the first specimen. Mr. PEPPER replied that there were not; the cyst wall was smooth internally. Mr. BUTLIN referred to a case under the care of Mr. Walsham, in which the growth was a spindle-celled sarcoma; it was possible for epithelial tumours to originate from the tunica vaginalis. Another case, removed by Mr. Willett, was also a sarcoma, and here the testicle and tunica vaginalis were perfectly free from disease.

Dr. NORMAN MOORE showed a specimen of Congenital Malformation of the Heart. The case was that of a boy aged three years, who was under Dr. Moore's care at St. Bartholomew's. The heart showed great hypertrophy of the right ventricle, the left ventricle being of normal size. The tricuspid and mitral valves were natural. The pulmonary artery was given off at the normal situation; at its root its external measurement was barely a quarter of an inch. Internally its valves were represented by a small cone projecting into the artery, with a perforation at its apex no larger than a medium-sized pin. The aorta was larger than natural, and measured three-quarters of an inch across (external measurement at its origin); its valves were normal, and its orifice communicated freely with both ventricles exactly over a circular orifice at the top of the ventricular septum, about three-quarters of an inch in diameter; the foramen ovale was also widely open. The ductus arteriosus was closed, and the distribution of the vessels of the aortic arch was normal. During life the child was deeply cyanosed, and when it had measles the rash had the appearance of a general purpura. The child was under observation from April 10th to Nov. 4th, 1884. When its heart was acting quietly a systolic murmur was audible all over the chest, most distinct at a point midway between the left nipple and the sternum. There was no thrill when the heart's action was irregular, owing to pulmonary catarrh, and then no murmur was audible. In addition to a deep general cyanosis there was great dilatation of all superficial veins, those of the eyelids being especially sinuous and distended. The veins of the fundus of the eye were very tortuous also. There was always an offensive discharge from the mouth, and the child sank rapidly with a necrosis of all the tissues of the right cheek, including a small piece of the superior maxillary bone. The fingers and toes were greatly clubbed. On cutting into them at the autopsy, the clubbed ends could be reduced by pressure to the normal shape. Microscopical sections of one of the terminal phalanges of the second right toe showed that the clubbing, while chiefly due to mere engorgement, was associated with some thickening of the walls of the blood-vessels. There did not seem to be any general increase of connective tissue. The mother had had another child cyanotic soon after birth, which died at the age of eighteen days. The cyanosis of this child was not noticed till some time after birth. Dr. William Hunter, in 1783, gave the first exact description in England of a heart with a small pulmonary artery and free communication between the auricles and between the ventricles. The cause of death is various in these cases. In the present one it is worthy of remark that death was due to necrosis, a change directly due to the defective conditions of circulation. In spite of its extreme cyanosis the child passed through an attack of measles with no more difficulty than a healthy child.

Mr. DAVIES-COLLEY showed photographs of a case of Synostosis of the Dorsal Vertebræ. The patient was a man aged thirty-two, whose father had rheumatic fever twice, and his mother died of phthisis, otherwise there was no history of gout or rheumatism. He was a sailor at the age of seventeen, and then began to suffer from severe rheumatic pains as the result of exposure to all kinds of weather. He was later on subjected to great alternations of temperature at a cement factory; later still he found great difficulty in rising after stooping, and was frequently exposed to the action of cold and damp. About eight years ago the back began to grow out, and he suffered from lumbar and abdominal pain. Nearly eleven years ago he had an attack of gonorrhœa, which caused no difference in the previously existing rheumatism. His height used to be 5 feet 6 inches, but was now 5 feet 2 inches. There was no tenderness on preseure over the dorsal spinous processes. The erector spinæ muscles were fairly strong. Difficulty was experienced in going upstairs. At the junction of the first rib cartilage with the sternum there was a prominent bony mass. The chest was very rigid and scarcely expanded half an inch in full inspiration. There was but an interval of two inches between the umbilicus and ensiform cartilage. The knee-jerks were normal. He improved under treatment with iodide of potassium. Similar cases had been recorded by Mr. Clutton, Dr. Allen Sturge, and Dr. Fagge. The disease was probably due to a chronic inflammatory change occuring in the periosteum and ligaments around the vertebræ, or possibly in some cases between the laminæ and spinous processes. There was possibly also some outgrowth of bone about the head and tubercles of the ribs, which would cause diminution in the thoracic movements. The gonorrhœa did not have anything to do with the causation of the disease, for the rheumatism was not worse when the gonorrhœa came on. Dr. WILKS thought that such cases were not uncommon, though but little recognised clinically. Many of the pains and other troubles which old persons experienced were due to such changes. It was very common to find various degrees of ankylosis between the vertebral joints which were of the nature of osteoarthritis. He referred to the case of a lady who suffered pain in the large occipital nerve, and in whom all the limbs were affected with chronic rheumatic arthritis. Dr. NORMAN MOORE said that he had shown in the last session of the Society specimens of the vertebræ of a Roman in whom the osteo-arthritic disease was exceedingly well marked. The vertebræ may be ankylosed by an overgrowth of bone between the dorsal spines as well as between the centra. He considered that the changes in young people were not the result of the same disease as that which occurred in old people.—Dr. GOODHART asked how far injury, as the carrying heavy loads on the back, could account for such conditions.—Dr. BARLOW thought that the specimens in the museums showing union of vertebræ by means of splints of bone, chiefly in front and at the sides, which kept the spinal column nearly straight, were of a different nature from those cases of spondylitis deformans where there was arching backwards of the dorsal spine with considerable curvature. He had seen four typical cases of spondylitis deformans. One was that of a volunteer, aged twenty-six, who had got damp and had severe backache after camping out; his height was diminished by five inches; the patient committed suicide owing to the intensity of the pains. In two other cases occurring in individuals aged about forty, gonorrhœa in one, and acute rheumatism in the other, preceded the spondylitis deformans, which was also associated with rheumatic arthritis. He had seen another case of spondylitis deformans where no signs of osteo-arthritis were present. The plaster jacket produced no benefit in either of the two cases in which it was used.—Mr. J. BLAND SUTTON said that he had seen changes in the spinal vertebræ of a camel exactly resembling those seen in man. Large masses of bone ankylosed the vertebræ together. There was no difference between the osteo-arthritic changes in man and those seen in animals. The extinct great Irish elk was a witness to the antiquity of the disease. Mr. DAVIES-COLLEY, in reply, considered that the disease in old people was different from that in the young. He did not agree with the suggestion of Dr. Goodhart that there was paralysis of the muscles supporting the spine.

Mr. BILTON POLLARD showed sections and drawings of a specimen of Epithelioma of the Upper Jaw removed by Mr. Christopher Heath, at University College Hospital, in October last. The patient was a man aged sixty. He had received a severe blow on the right cheek eight years previously. Nine months before admission his nose began to bleed on the right side, and three months later the right cheek began to swell, and later the right nostril became blocked. On admission a swelling of the right cheek was observed, but the skin over it was not implicated. The hard palate was bulged close to the alveolus on the affected side; there was no sinus between the mouth and antrum; the teeth were sound, and the alveolus healthy. There was no enlargement of the lymphatic glands, and no family history of new growths. At the operation the growth was found to fill the antrum, right nasal fossa, and sphenoidal sinus. The patient made a good recovery, and left the hospital in four weeks. The growth was greyish-white in colour and of firmish consistence, with bands of denser tissue running through it. The greater part was composed of tubes of small cells ramifying through a hyaline and finely fibrillated stroma; the tubes anastomosed freely, and islets of colloid degeneration were scattered within them; the tubes were without lumina. Here and there cells of a larger size were seen, evidently of epithelial type. The stroma was really composed of spindle-shaped cells. The tumour had

alliances with the plexiform sarcoma of Billroth, but was much more like the tubular epithelioma of Cornil and Ranvier. Clinically, the tumour had resemblances to the "boring epithelioma" of M. Reclus[1] and to those cases shown by Mr. Butlin in 1881.

Dr. CARRINGTON read for Mr. Lane a paper on Suppuration in many of the Joints of an Infant eight weeks old, who had had specific eruption all over the body and snuffles. There was much emaciation. Treatment was effected by mercury and stimulants without result. During life only the left elbow-joint was swollen. At the autopsy suppuration was found in the right hip and right shoulder and both elbows; these were distended with pus. The ribs were markedly beaded; there was no softening to be detected between the epiphysis and diaphysis. The changes were most marked about the humerus and ulna of the right elbow. No suppuration in the thymus was found. A firm yellowish-pink coloured gumma was seen in the upper lobe of the right lung, and in the liver there were one or two whitish patches of doubtful nature. The case seemed to be rare and unlike those described by M. Parrot. One recorded by Dr. Lees in the Clinical Transactions for 1880 was nearly allied to it.

The following card specimens were shown:—Dr. Charlewood Turner: Horseshoe Kidney and Sarcoma of both Adrenals. Mr. John Poland: Suppurating Bronchial Gland opening into the Œsophagus and Left Bronchus. Dr. Norman Moore: (1) Disease of Sacro-iliac Joint following Parturition; (2) Renal Tumour composed of Cholesterin; (3) Aneurysm of the Anterior Aortic Valve. Mr. M. Sheild: Rectal Polypus. Two recent specimens were shown:—Mr. M. Sheild: Morbid Growths, probably Gummata, in the Liver of a Woman, aged twenty-four. Mr. Battle: Cyst containing Creamy Fluid, removed by Mr. Sydney Jones from the intestinal wall of a woman, aged twenty-five.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Jan. 14th, Sir Joseph Fayrer, K.C.S.I., M.D., Vice-President, in the chair.

Surgeon-General MOORE read a paper on the Constitutional Requirements for Tropical Climates, with special reference to Temperaments. After remarking that in former times more attention was paid to temperament than is now the case, the author proceeded to prove by reference to the "Vedas" that the Aryans when they descended into India, 5000 years B.C., were white in colour; their habits and constitutions being then adapted to a northern climate. But the influence of warm climates impresses certain peculiarities on those who inhabit them. Exposure to the heat of a tropical climate tends to bronze the white skin; unless the possessor unfortunately becomes subject to that slow blight of the constitutional powers manifested by a diminution of red blood-corpuscles, in which case the skin is blanched. Then there is a positive diminution of inspired oxygen, owing first to the expansion of the air from heat, and secondly to the lessened number and force of respirations, consequent on the lassitude experienced and on the smaller amount of physical exertion taken in the tropics, where actual necessaries in the shape of food are produced under the minimum of labour. Doubtless, the Aryan Hindoos, once meat-eaters, left off consuming flesh as a desideratum of residence in a hot climate, and probably as a presumed means of maintaining the white skin on which they prided themselves. The Brahmins, who wrote the "Vedas," must have been intellectually capable of appreciating the evil of too much carbonaceous food in a tropical country, although not reasoning the matter out by the light of nineteenth-century science. However this may be, there is no doubt that the Aryans, once white, with northern temperaments and habits, have, during the lapse of ages, by the survival of the fittest, been converted into the modern Hindoo, with his typical temperament, which may be regarded as a compound of the nervous and bilious, and in which all the inhabitants of Hindoostan, whether Aborigines, Hindoos, or Mahomedans, partake; and when we recollect that in one or two generations Celts and Saxons, Teutons and Danes, *cum multis aliis*, are converted into the sallow typical inevitable Yankee, the change during thousands of years of the light Aryan into the dark Hindoo seems facile. Now, theoretically, it would appear that the European, who in type and temperament most closely resembles the natives of India, would be best fitted to encounter the adverse influences of a tropical climate; and, practically, this appears to be the case, as Europeans marked by the bilious or bilio-nervous temperament usually enjoy the best health in India. The term bilious is a misnomer, as implying in persons of that temperament a tendency to hepatic derangement which does not exist in any extraordinary degree; the bilious appearance depending on a participation in that cutaneous deposit of carbon marking the dark races. But there must be no predominance of the nervous temperament, as a highly sensitive and sympathetic nature is not most conducive to health and happiness, when submitted to the daily ills and irritations of tropical life. A French physiologist is credited with saying that "If you want long life, you should possess a bad heart and a good stomach." Without endorsing this assertion, it may be stated, with certainty, that a highly nervous organisation, especially if, as is often the case, associated with feeble digestion, is not fitted for prolonged tropical residence. The temperament next best fitted for the tropics is the sanguine, perhaps explainable by the somewhat less liability of individuals of this type to tropical anæmia. But, on the other hand, there is tendency to hepatic affection, and the sanguine temperament enduring only for a period may rapidly or suddenly give way. The longer, however, persons of sanguine temperament live in India, the more decided is the change which takes place towards the bilious variety, explainable by a consideration of the general effect of a tropical climate on the system of the European, which is much the same as that converting the ancient Aryan into the modern Hindoo. Discarding such hypothetical causes as marsh miasmata and telluric influences, the author gave reasons for regarding *heat* as the principal factor in producing the changes, so often of a deteriorating nature, which take place in the system of the European sojourning in the tropics. Thus, temperaments become associated with acquired diatheses—as the scorbutic, the malarious, and the syphilitic, all of which should forbid tropical residence. The latent scorbutic taint is extremely prevalent in India, and as there is a pathological resemblance between gout and scurvy, the system tainted by the latter is extremely like to develop the former, and therefore hereditary tendency to gout should be regarded as against the advisability of a tropical career. Again, an hereditary tendency to hæmorrhage should be similarly regarded; for bleeding from the nose and gums being the ordinary manifestations of the hæmorrhagic diathesis, and also of malarious and scorbutic taints, it is easy to conceive how the latter, being established, may excite the dormant diathesis of the former. Hereditary tendency to insanity or epilepsy should also unfit for tropical residence, both of which are liable to be excited by heat. There is another malady which, although not regarded as hereditary, should unfit for tropical residence, and that is albuminuria. Years back hot climates were regarded as favourable for the first stage of renal affections. Experience, however, has proved that tropical countries should be forbidden to all who have passed albumen, unless from accidental causes. Idiosyncrasy, especially when it shows itself in an inability to take quinine, should unfit for Indian life. So should the deadly fear of disease, which causes some people to see danger everywhere, and, like Voltaire, to regard the atmosphere as "a blue and white mass of noxious exhalations." Age and sex are important considerations. Persons possessing the suitable temperament may proceed at a younger and remain till a later age than those of opposite temperament. The period at which officers are required to vacate active employment in the public services is fifty-five, which even in India is too early. For it must be recollected that such men represent the survival of the fittest, men who supported the burden of the day under which so many comrades succumbed, and who may therefore be credited with more than the average *vis vitæ*, with prudence of life, and with the suitable temperament. As regards sex, it was observed that, if it is desirable that males should not proceed to the tropics before the growth of the body is matured, it is especially desirable that females should not do so until the growth is matured, and the periodical functions are firmly established. Dr. Moore concluded his paper by lamenting the absence of ordinary care evinced for themselves by Europeans generally in India. In the discussion which followed Sir Joseph Fayrer, Surgeons-General Manifold and Cornyn, Drs. Lawson, Dickson, and Dow took part.

[1] Progrès Médical, 1876.

MEDICAL OFFICERS OF HEALTH SOCIETY.

AT a meeting of this Society held on Dec. 19th, 1884,

Mr. HENRY ARMSTRONG read a paper on the Status of the Medical Officer of Health as a Criterion of Sanitary Progress, The author remarked as follows:—A correct idea of the public desire for sanitary progress is to be formed by the position accorded to medical officers of health. In the present state of opinion the post of a health officer is one of devotion and self-sacrifice without adequate return. He is doing good work and his action is approved at head quarters, but the feeling among health officers in general is one of disappointment with their position. The causes of dissatisfaction are external and internal to the body of officers of health. The former include the anomalies of sanitary districts as regards area and population to be supervised, the amount of attention to be bestowed on his district by the officer, the terms of appointment, irregularities of remuneration in different districts, and smallness of salary as compared with other public professional officers, want of proper consideration for the office and officer on the part of local authorities, as shown by their treatment of his advice (reports, &c.) and the amount of authority given him; opposition between the health officer and the inspector of nuisances, sometimes promoted; the personal relations existing between the health officer and individual members of his authority; his remuneration is generally inadequate, and he is sometimes tempted to take other and even unprofessional duties to eke out a slender income. His salary in many instances is liable to reduction, generally owing to the short period for which he is engaged; he is exposed to frequently recurring risk of loss of office without cause on his part; he has no prospect of pension with advancing age, and his relations with the public are difficult. Duty brings him into conflict with private interests. He does not receive sufficient support from those in authority. Internally, the causes of dissatisfaction are, among others, that medical men accept appointments at unfairly low rates of remuneration and without due regard to the responsibilities of the duty they undertake to discharge. The foregoing circumstances react on each other, both on the part of the public and the practitioner; the cause of sanitation, and, *pari passu*, the status of the officer practising it, suffer. The status of officers of health may be improved (1) by equalising the health appointments through compulsory combination of small districts, and by appointing superintendent medical officers of health over entire counties or groups of counties; (2) by the Local Government Board exercising more control over the appointments and duties of officers; (3) by local sanitary authorities being deprived of the option of ignoring the sound advice of their health officers; (4) by extending the authority of health officers; (5) by making his recompense and prospects equal to those of other professional men on his own level; (6) by giving the officer satisfactory tenure of his appointment. The holding of health appointments by private, general, or consulting practitioners is not desirable. The salaries of the appointments should be sufficient to render such a mode of increasing the income unattractive. The officer may with advantage hold certain other public appointments relating to hygiene—e.g., those of medical superintendent to a hospital for infectious diseases, coroner, public vaccinator, superintendent, registrar of births and deaths, lecturer on hygiene at a medical school, examiner for university degrees in sanitary science. He may also under certain circumstances act as public analyst if he has received proper and sufficient training for that office, and if he has assistance so as to prevent the work from interfering with his other duties. He should not accept such offices as superintendent of scavenging, inspector of nuisances, veterinary inspector, &c. The intending medical officer of health of the future should undergo a term of pupilage and assistancy with a health officer, and before applying for full appointment should be able to produce a distinctive sanitary diploma or degree, such as that of Doctor or Bachelor in Hygiene, by examination after completion of a recognised curriculum. The paper concluded by recommending that the questions raised be referred to the Council for their report with the view of practical action being taken by the Society.—In the discussion which followed, the President, Drs. Gibbon, Walford, Saunders, Seaton, and Bate, and Messrs. Jacobs, Furnivall, Blyth, and Hartt took part.

WOLVERHAMPTON DISTRICT MEDICAL SOCIETY.

AT the meeting of the above Society, held on Jan. 8th at Wolverhampton,

Mr. VINCENT JACKSON read a paper on a Cheap and Ready way of Treating Club-foot. Having given an able and interesting summary of the history of the subject, which dated from 1837, he enumerated the varieties of the deformity and divided the treatment into operative, manipulative, and mechanical. For the latter purpose he strongly recommended the use of plaster-of-Paris, as being far cheaper and quite as effectual as the more costly special instruments. Mr. Jackson then demonstrated his mode of procedure.

Mr. A. E. CHESSHIRE read a communication on the Value of Cocaine as a Local Anæsthetic for Operations on the Eye, and stated that he had used it in forty cases, and found that it abolished or so lessened pain that most ophthalmic operations could be performed with comfort both to the patient and to the operator. He used a 5 per cent. solution applied every five minutes.

Mr. JACKSON exhibited a specimen of an Aneurysm of the External Iliac Artery with ligature of that vessel, the patient having died in twenty-six hours from acute gangrene.

Dr. DINGLEY exhibited a specimen of Cancer of the Kidney, the chief interest of which was that no trace could be found of the other kidney. The renal artery, ureter, and vesiculæ seminalis were also missing, but there were two suprarenal bodies and two testicles. Also a specimen of a new growth in the liver, probably of a malignant character, and the intestines showing perforation, occurring in enteric fever.

In the discussion which followed the papers Dr. Lycett, Dr. C. R. Smith, and Mr. Jackson took part.

Reviews and Notices of Books.

Elementary Text-book of Zoology. General Part and Special Part: Protozoa to Insecta. By Dr. C. CLAUS, Professor of Zoology in the University of Vienna. Translated and Edited by ADAM SEDGWICK, M.A.; assisted by F. G. HEATHCOTE. With 706 Woodcuts; pp. 615. London: W. Swan Sonnenschein and Co. 1884.

THIS work, by a distinguished naturalist, represents the present state of zoological knowledge. It has been translated into French by M. G. Moquin Tandon, who has, moreover, made considerable additions to the original. We are glad to see it in an English dress, and, after having compared many passages with Claus' treatise, to give our testimony that Messrs. Adam Sedgwick and F. Heathcote's translation is executed with singular fidelity and idiomatic clearness. The general plan of the work is similar to that of Rymer Jones's treatise on the Animal Kingdom, a work that at the time it was written was a very good epitome of zoology. The general part, which extends to nearly 200 pages, discusses many subjects, however, which were not thought of in the days of Rymer Jones, and which are the outcome of modern research. Referring to the origin of life, Professor Claus speaks very cautiously, merely stating that in the present state of our knowledge there is no evidence to show that an independent abiogenetic generation (generatio æquivoca, or spontaneous generation) actually takes place even in the simplest and lowest forms of life, although very recently some investigations, as those of Pouchet, have led by the results of remarkable but equivocal experiments to the opposite view. "The existence of the generatio æquivoca," he observes, "would offer a very important service to our contention for the physico-chemical explanation; *it even appears to be a necessary postulate in order to explain the first appearance of organisms*," a statement that indicates the strong tendency which exists amongst many naturalists to refer the beginnings of life to purely natural causes. The "cell" is stated to consist of a small lump of a semi-fluid albuminous substance

(protoplasm), containing as a rule a dense or vesicular structure—the nucleus; which is frequently surrounded by a peripheral structureless membrane. In this definition the term albuminous seems open to question, since protoplasm does not present the chemical characters of albumen, and the nature of the nucleus might have been better given. It is interesting to read Professor Claus' definition of an animal. It is, he says, to be defined "as an organism provided with the power of free and voluntary movement, and with sensation, whose organs are internal, and are derived from a development of the internal surfaces of the body; which needs organic food, inspires oxygen, changes potential energy into kinetic, under the influence of oxidation processes in metabolism, and excretes carbonic acid and nitrogenous waste products."

A chapter is devoted to the organisation and development of animals in general, in which after the characters of cells and the tissues derived from cells have been considered, the subjects of correlation of organs, the structure and functions of the compound organs, development, the alternation of generations, polymorphism, and heterogamy are successively *but briefly* discussed. The fifth chapter is occupied with an account of the theory of natural selection, and the various evidence in favour of that of descent is given. All this part is so interesting, and places so well before the reader the concepts of modern biology, that it deserves to be studied, even by those who do not wish to follow the details of the structure of the different orders and families of animals that are subsequently given.

We venture to take one example of the mode in which a group of animals is treated by Professor Claus, and we select the "Trematoda" from the general interest they possess. Professor Claus defines them as "elongated and usually segmented Platyhelminthes without mouth or alimentary canal, with organs for attachment at the anterior extremity." He commences their description by pointing out that, whilst originally regarded as single animals, the view advanced by Steenstrupp that the proglottides must not be disregarded, and that whilst the individuality of the tapeworm may be justly insisted on, the subordinate and morphologically more restricted degree of individuality of the proglottis must also be admitted. A general description of the tapeworms follows, the characteristic features of the Bothriocephalus, Acanthobothrium, Tetrarhynchus, and Taenia being incidentally mentioned. The successive stages of development are then described, from the egg, through the embryo stage, and the formation of a vesicle which converts it into a bladder worm with one (Cysticercus) or several (Coenurus) hollow buds, but still sexually immature animal. The bladder worm, it is then shown, entering the alimentary canal of another animal, loses its vesicle by the action of the digestive fluids, whilst the head or scolex, becoming free, gradually produces a chain of proglottides by a form of sexual production. The differential characters of the Taenidæ and of the several families included under that name are then given. The account of the Cestoda is illustrated by fourteen woodcuts. The manner in which the volume is got up by Messrs. Sonnenschein reflects great credit upon them, the paper, the type, and the impressions of the very numerous and admirably illustrative drawings being alike excellent.

The Principles of Ventilation and Heating, and their Practical Application. By JOHN S. BILLINGS, M.D. Pp. 216. London: Trübner & Co. 1884.

THE author states the object of this work to be "to present the subject [of heating and ventilating buildings] in such a way that architects will appreciate its importance in their work—and understand its difficulties and the general principles which should guide them in endeavouring to overcome these difficulties—more fully than many of them seem to do at present." As might be anticipated of any work by Dr. Billings, it bears evidence of a careful study and practical knowledge of the subject. But it has been written chiefly with reference to conditions in the Northern States of America, and is therefore not so applicable as it might otherwise have been to this country. Of this Dr. Billings is well aware, for he observes: "The fact that good ventilation is expensive is not so well recognised as it should be, for the reason that much of our literature on the subject is furnished by English authors, who write with reference to the climate of England. This climate is very different from our own, being much more uniform. ..... In this country rooms must be kept at a temperature of from 68° to 70° F. to ensure the comfort of the occupants; while in England 60° F. seems to be the recognised standard. Open fireplaces and grates can therefore be used there more extensively than here, and in arranging apparatus for heating by indirect radiation it is necessary to provide more heating surface than is called for by the specification of English engineers." His remarks on the heating and ventilation of churches, theatres, and large public buildings deserve the careful consideration of architects and others entrusted with their plans and erection, for though great progress has of late been made, and some recent examples show how much may be done, it must be admitted that, as a rule, the condition of places for public assemblage is still capable of much improvement. He has devoted a chapter to the ventilation and heating of schools, of which he says that "of all classes of buildings in the United States, public or private, there are probably none which are in such an unsatisfactory condition as regards their ventilation." We doubt whether in this country the same remark might not be justly made, and we would recommend the subject to the notice of members of school boards, and of all who are interested in the welfare of the rising generation. The subject of the heating and ventilation of hospitals has received more than an average amount of attention from architects; but it is evident from the author's observations and his description of the methods adopted in various recently erected hospitals that there is still much room for improvement, both as regards efficiency and expense. We trust that Dr. Billings' work may receive the attention it deserves from architects and others in charge of or responsible for the construction of public buildings, feeling assured that it will tend to promote improvement in a direction in which it is much needed. The book is illustrated by woodcuts and has the advantage of an index, which might, perhaps, have been advantageously made more copious.

Plant Lore, Legends, and Lyrics. By R. FOLKARD, jun. London: Sampson Low, Marston, Searle, and Rivington. 1884.

FOLK-LORE has enjoyed a considerable amount of popular favour during the last few years, and numerous articles on the folk-lore of plants in particular have found their way not only into journals devoted to horticulture, but even into some of the leading daily newspapers. The volume under consideration is the result of an accumulation of material originally intended for a similar purpose, but which, owing to the discontinuance of the journal in which it would have been issued, is now published in the present form, with numerous additions and an excellent index. It will doubtless be found very much more convenient for reference in the form of a complete work, especially as it is now arranged, consisting in the first part of sixteen chapters under different headings, and in the second of the plants arranged in alphabetical order under their vernacular names. The first part contains a good deal that is of interest to students of the history of medicine and materia medica, particularly the chapters bearing the titles of "Plants

and the Planets," "The Doctrine of Signatures," "Magical Plants," "Plants of the Devil," &c. The work is got up in an attractive style, is illustrated with copies of quaint woodcuts from old herbals and books of travels, and forms a very suitable book for a birthday gift to anyone interested in plants and their uses. The book bears evidence of careful revision, being unusually free from typographical errors. In a few cases, however, the botanical names, especially those of a specific character, have been omitted. The very natural error of confounding the pita or Mexican aloe (Agave Americana) with the Barbadoes aloe (Aloe vulgaris) is one of the very few botanical errors noticeable.

Diseases and Injuries of the Eye. By GEORGE LAWSON, F.R.C.S., &c. Fifth Edition. London: Renshaw. 1885.

THE issue of a fifth edition of this excellent work is testimony to its sustained popularity. In preparing a new edition Mr. Lawson has spared no pains to make his work representative of the best contemporary knowledge. Many articles have been rewritten, and several new subjects have been added. Indeed, every page shows evidence of conscientious revision. With the fullest confidence we can continue to recommend Mr. Lawson's manual, in spite of many rivals, as in most respects the best in our language, whether for the student or for the practitioner.

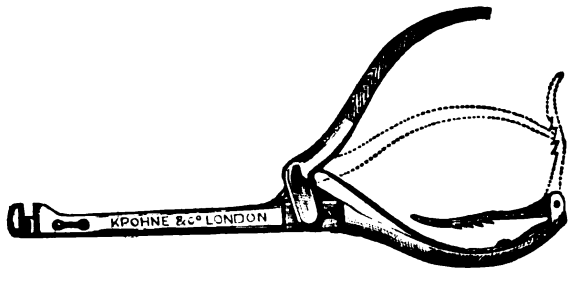
Street's Indian and Colonial Mercantile Directory, 1884-85. London: Street and Co.

WE have received a copy of the tenth issue of this work, which is calculated to prove of immense advantage to all who have business connexion with any or all of England's foreign possessions. It contains trade returns, tariffs, populations, and full particulars of the steam and other communications with the various places treated of; the leading merchants, traders of every class, and professional men are fully enumerated. A concise description of each county and town is furnished, along with a list of the principal products. As in previous years, maps are in this issue given of all the principal countries mentioned in the letterpress, and particulars of the various railways in operation, or in course of construction, are supplied where practicable.

New Inventions.

HAGEDORN'S SURGICAL NEEDLES AND NEEDLE-HOLDER.

MESSRS. KROHNE & SESEMANN have submitted to us some excellent surgical needles and a very convenient needle-holder, which have been devised by Dr. Hagedorn of Magdeburg. The needles are semicircular in shape, the



section of the stem being an oblong parallelogram of the same thickness throughout its length. The point has a single cutting edge on its convex surface. The advantages which these needles have over the curved needles in general use are that the puncture they make is a fine slit at right angles with the edge of the wound to be united and therefore when the suture is tightened the edges of the puncture are approximated, not made to gape; the puncture of the needle is also at right angles to the surface of the wound, and the suture approximates the whole thickness of the parts through which it is passed with equal tension; and the needles are stronger and much less liable to break when held in a holder than those in common use. The needle-holder is very simple in construction; it grasps the flat surfaces of the needle, and can seize and hold the point as securely as any part of the stem. The jaws are closed with a lever handle, which can be fixed by a ratchet. For special purposes these holders are made of different lengths and shapes, but anyone who will use them will soon be convinced of their great convenience and merit.

THE METROPOLITAN ASYLUMS BOARD.

A REPORT, dealing with the operations of the Metropolitan Asylums Board, has been recently issued. This is the first time that any attempt has been made to bring the whole work of this body into one view, and the handbook commences with an account of the provision made for the care of harmless lunatics. The first asylum founded was that at Leavesden, near Watford, and the whole cost of the asylum's buildings, and the land on which it stands, upwards of eighty acres, a farm being worked in connexion with the asylum, is set down at £177,818. The accommodation provided is for 1100 females and 900 males, the cost being £88 16*s.* a bed. The sister asylum at Caterham stands in the midst of 154 acres, and the expenditure upon that asylum up to date has been £192,382. This asylum provides for 2050 patients—namely, 1150 females and 900 males. The third and fourth asylums for this class of patients are at Darenth, in Kent, where, for the imbecile classes alone, the managers have acquired 173 acres. One asylum here is for imbecile children. There are upwards of 600 children in this asylum, many of them hopeless idiots, but some capable of being trained into work of a useful character. The second asylum is for adults, and there are now 900 of the same character of patients as fill the Leavesden and Caterham asylums. The cost of the asylums and lands at Darenth was £247,951. Thus, in all the Board has about 5500 imbecile patients under its care. The provision for fever includes five asylums, which find beds for 951 patients, and provision is being made for 512 convalescent patients at Winchmore-hill, where the land has been acquired, and the building of the asylum is proceeding. The Eastern Homerton Fever Asylum cost, for land and buildings, £87,772, and provides 300 beds for fever. The South-Western Asylum, Stockwell, which provides 228 beds for fever, cost on the whole £104,094, and additional works are being carried out now to the cost of £2000. The North-Western Asylum (the Hampstead Hospital) cost £54,820, and there has been additional expenditure of late to the sum of £3200. The asylum has 150 beds for fever patients, and a few beds for such severe small-pox cases as arise in the district. The Western (Fulham) Asylum, which affords 90 beds for fever cases, cost £64,257, and further expenditure is being incurred. At the South-Eastern Asylum (New Cross-road) there has been an expenditure of £70,835, and accommodation is provided for 150 fever patients. In each of these asylums a limited number of beds is provided for the reception of small-pox patients.

The provision for small-pox, apart from the other asylums, has been of a very complete character. Accommodation has been provided for 1600 patients to be treated at one time, the hospital ships, the camp at Darenth, the Plaistow hospital, and five other places being used for the purpose in the emergency. The ships have cost £28,129, the ambulance station in the east of London has cost £10,552, the Darenth camp has cost £34,561 in establishing and £50,942 in maintaining, the Plaistow asylum has cost £4692, the ambulance steamers and wharves have cost £6173, the south-eastern ambulance station has cost £4661, and the western one, exclusive of construction, has cost £3961. The report concludes with a statement of the work done in connexion with the *Exmouth* training ship and a complete account of the expenditure, the cost of the patients in the various asylums being given in detail.

THE LANCET.

LONDON: SATURDAY, JANUARY 24, 1885.

LAST week we published an account of the meeting of the Medical Society, at which Dr. HERON showed the differences between cultivations of Dr. KOCH'S comma bacillus of Asiatic cholera and Drs. FINKLER and PRION'S bacillus of cholera nostras. It will be remembered that the most striking of these differences lay in the fact that whereas KOCH'S organism liquefied nutrient gelatine but slowly, that of FINKLER and PRIOR did so rapidly and extensively, so that whilst in the case of the latter the track made in the gelatine by a platinum wire used for inoculation was in the course of a few days wide and stocking-like, in the case of Dr. KOCH'S organism it presented the appearance of a mere thread. The value of this diagnostic mark of the comma bacillus of cholera has, however, been very materially diminished by the publication within the last few days, in BÖRNER'S *Medicinische Wochenschrift*, of a very carefully drawn up account of the discovery by Dr. DENEKE, of the Hygienic Institute at Göttingen, of a comma-shaped organism in some stale cheese. Dr. DENEKE instituted careful comparisons between the commas which he thus found and those of KOCH on the one hand, and of FINKLER and PRIOR on the other, and found that "as regards its morphological characters as well as its mode of growth in, and action upon, nutrient gelatine, the cheese comma approximated much more closely to the bacillus of cholera than to the other." A minute account is given of its microscopical characters, of its mode of growth in meat broth and in gelatinised material in test tubes, and also when spread out on glass plates, but as this agrees in most particulars with the accounts which have already been frequently published concerning the cholera microbe, it is not necessary to reproduce it here in its entirety.

It is mentioned that in the earlier stages of growth the "colonies" of these cheese commas appear to the naked eye very like those of the cholera commas, but that under a power of one hundred diameters some slight differences may be detected. In test-tube cultivations in gelatine the resemblance is stated to be still closer, and "it is often difficult to distinguish cultivations of the cheese bacillus in the earlier stages from those of the choleraic bacillus in a somewhat more advanced stage." As in the case of KOCH'S bacillus, the growth along the track of the inoculating wire is thread-like, though somewhat wider, and the upper part of the funnel-shaped cultivation is similarly characterised by the development of an air vesicle. Dr. DENEKE did not succeed in developing his commas on potatoes, but he found that when cultivated in agar-agar, and in solidified blood-serum, no distinction could be made between them and those of cholera, or of cholera nostras, either as regards their mode of growth, or their action on the medium. Dr. DENEKE, however, considers the cheese organism to be physiologically distinct from that of cholera, although he appears to base, perhaps, his chief conclusion that this is so on the results of some experiments on animals. Following the example of MM. NICATI and RIETSCH, he introduced a small quantity of the cheese commas directly into the duodenum of two guinea-pigs, as also a small quantity of a cultivation of choleraic commas into the duodenum of two other guinea-pigs. The two animals of the former experiment recovered, the two of the latter died; but it is added that as one of these guinea-pigs succumbed within six hours (consequently before it could reasonably be expected that the microbes could have manifested their assumed virulent properties), and also because a portion of the material introduced had escaped into the peritoneal cavity, it is not claimed that this experiment proved anything.

Judging from the very contradictory results which have from time to time been announced as a consequence of infecting animals with choleraic material, and judging also from the circumstance (to which we drew prominent attention a short time ago) that Dr. EMMERICH of Munich had succeeded in producing cholera-like pathological lesions by means of a totally different microbe, no great importance can be attached to the death of the other guinea-pig referred to by Dr. DENEKE. It is, however, clearly manifest that he has drawn attention to an organism which, both morphologically and physiologically, very closely resembles the comma bacillus of cholera, even if it be not absolutely identical with it.

The importance of the observations is materially enhanced by the fact of the microbe having been detected in one of the ordinary articles of our food; it must therefore presumably be more or less constantly introduced into the alimentary canal. It is now well known that organisms of a similar type are frequently present in the mouth in health, but, strange to say, it would appear that they are by no means to be so readily detected in normal alvine secretions. It is possible that during *health* the action of the juices of the mouth and stomach is inimical to their further development; as indeed appears to be the case with Dr. KOCH'S comma microbe, seeing that it does not develop in the intestines of animals when administered by the mouth, and hence the necessity which has arisen for introducing it directly into the duodenum for experimental purposes. This is a phase of the question which Dr. KOCH and his supporters have completely ignored when comparing the physiological properties of various comma-shaped bacilli. It is already abundantly manifest that organisms of this character are by no means so restricted in their distribution as was supposed at the time when one of the tribe was fixed upon as being the cause of cholera. Much has been learnt since then, but there is still much to be done; and workers in this field of research may rest assured that every addition which they make to our knowledge of these curved microbes will be warmly welcomed at the present time, not only by the profession but also by the public at large.

INFLAMMATION, in itself a purely mechanical derangement of the circulation, presents many varieties, in which its basal type of action is more or less altered and complicated by the advent of contagion. These lie, one may say, upon the borderland between local and communicable dis-

ease, and present examples of the passage of one form into the other, so that we have come to talk of inflammation as affording a nidus for septic development. The cases of a common cold, of "idiopathic" erysipelas, of simple and rheumatic tonsillitis, might all be quoted in illustration. Treatment is necessarily much affected by these considerations. One finds that one has to deal not only with an obvious effect which is actively destructive of the tissues which it implicates, not only with so much of mechanical causation as this represents, but with a further more subtle cause, a "germ," which is at least the vehicle of a still more remote and perhaps original stimulus. Sometimes it would seem that the cause had been overwhelmed by the created morbid action—that is, that the implanted poison, if not rendered inert, had been largely supplanted in importance by the tissue irritation to which it gave rise. There is reason to doubt whether in such a case its primary force has been greater than that of mere mechanical irritation. In other instances, it lives, multiplies its power, and works, destructive but indestructible, exhibiting all the characters of sustained malignancy, in addition to being readily transferable by contact from one subject to another. The former group of symptoms exemplifies the meaning of the old term "inflammation," the name of a result; the latter we take to be commanded and absorbed by its cause, and we call it "septic disease." Yet among the milder cases not credited with contagious properties one finds examples of transference of the disease between associated persons, as also, probably, in the undoubtedly malignant class, instances of contact without such transference. These facts show that the borderland of infection to which we have referred is a fairly wide one, presenting degrees of risk. They also give some colour to the opinion that there has been an evolution in its history in the direction of aggressiveness, and that bacilli and spores are, without distinction, media of transit rather than the sole causes of the infectious properties. The treatment of ophthalmia may serve to indicate the bearing of these points in pathology on therapeutics. In the various forms of this disease there are grades of contagion and of virulence. Even the comparatively innocent catarrh, which is not usually regarded as being contagious, seems occasionally to assume a severer form, and is communicated to the healthy eye, just as the action of eczema is sometimes engrafted on a sound skin. The ophthalmia of infants, the much more destructive and poisonous purulent form seen in adults, and the gonorrhœal variety also show ascending series of infectiousness. It will be said that for the latter varieties a special germ is active in each case. There is room to doubt, nevertheless, how far the differences attributed to these are peculiar to themselves, and whether they are not of degree only, rather than of kind. In any case, it is a characteristic of this class of disease that the basal inflammatory change continues the most prominent feature. The uniform efficiency of nitrate of silver is a proof of this. The germ, whatever it may be, is extinguished by a drug directed against the mechanical changes it has caused. This very remedy, moreover, has little or no repute where septic poisoning is the predominant evil. It cannot control the rapid tissue infection then apparent. Ocular diphtheria does not benefit by it, but antiseptic measures are here everything. Thus we seem to pass by stages along one morbid process from states of weak infectiveness but high local irritability, to others allied in type but highly contagious. Treatment must follow a corresponding course, and its results furnish in themselves, we cannot but think, a guide to the true pathology.

WE not unfrequently receive inquiries as to whether a medical officer of health should or should not be allowed to remain in private practice. One such inquiry we answered briefly in our last week's issue; but the subject is again urged upon us in another form. On the question generally, we have no hesitation in saying that under ordinary circumstances we should prefer to see medical officers of health independent of private practice; but, as matters now stand, we are quite certain that the universal application of this rule would in many parts of the country be distinctly prejudicial to the interests of public health. In the first place, the number of medical men who have by examination and otherwise fitted themselves for holding the post of officer of health is by no means large, and so long as this is the case it is better that towns and districts be officered by men of ample experience in the various branches of their profession, and who are still in practice, rather than by others who are less competent, but who would be willing to give their whole time to their official duties. Then, again, there are officers of health who, though in practice, are unquestionably competent to discharge the duties pertaining to the post they occupy, and whom we should be sorry to see replaced merely in order that they might be succeeded by others who have seen little or no practice, and who intend altogether to discard the ordinary work of their profession. There is a further point which we think of even greater importance. We hold that no district, whether urban or rural, has a right to demand the entire services of a competent officer of health unless it is prepared to guarantee a salary sufficient for the payment of such services; and we have occasionally seen with regret that some medical men, in their desire to get a footing in the sanitary service of the country, have undertaken to give themselves wholly to sanitary work at salaries which they should have regarded as hardly ample to command their services for more than one or two days in the week. Some districts, again, are either too small or too sparsely populated to give occupation to an officer who has no other professional calls upon his time, and in such districts private practice, within certain limitations, may be useful both to the officer and to the district which he serves. But where an adequate salary can be ensured we feel strongly that the ordinary practitioner is likely to find himself hindered in his work as health officer, both by the calls which in practice are made upon his time, and by the difficulties which he will experience in dealing impartially in his official capacity with those upon whom he is also dependent in his practice. When, after a lapse of some years, there shall be a sufficient number of properly trained practitioners to fill the many posts of officer of health, we shall hope to see most districts officered by those who are independent of practice; and where districts are not in themselves capable of paying such salaries as should command the entire services of a skilled officer, we trust that the authorities may in advance combine with adjoining districts, so that they

may collectively offer a proper remuneration for the services they require. Until such a time arrives each case will have to be judged on its merits.

IN the December number of the *Revue de Chirurgie* is a translation of a Russian paper by Dr. SKLEFASSOWSKY, in which he relates the case of a man on whom he has performed an osteoplastic operation first devised and practised by Dr. WLADIMIROFF of Kazan, by whose name it may perhaps best be known. The operation consists in the removal of the posterior part of the foot and the ankle-joint and the union of the anterior part of the foot to the leg, so that the foot is in a line with the leg, and the patient subsequently walks upon the heads of the metatarsal bones and the fully extended toes. The method of procedure is as follows:—An incision is made straight across the sole on a level with the middle of the scaphoid bone; on each side this incision is continued up to the malleolus, and then straight across the back of the ankle. The incisions are all carried down to the bone, and the ankle-joint is entered from behind and disarticulated. This done, the heel is seized, and the soft parts of the dorsum of the foot are carefully separated from the bones, care being taken not to expose or injure the dorsal artery of the foot. The transverse tarsal joint is now to be opened and disarticulated, and the os calcis and astragalus removed. The articular surfaces of the cuboid and scaphoid, and the lower ends of the tibia and fibula, are to be sawn off, and the foot is then to be applied to the end of the leg, and first the bones, then the soft parts, united with sutures.

The advantages claimed for this operation are, that while permitting of the removal of diseased parts it preserves healthy structures, and is not such a mutilation as is a SYME'S or PIROGOFF'S amputation, or an amputation through the lower third of the leg. The result is stated not to be a great deformity, the line of the limb is preserved, and the foot forms an excellent basis of support. The cases for which it is suitable are intractable ulcers of the heel, disease of the tarsus limited to the os calcis and astragalus, and new growths similarly limited. SKLEFASSOWSKY performed the operation for a very chronic ulcer of the heel, which had resisted all treatment for nine years, and which invalided and crippled an otherwise robust man. PIROGOFF'S amputation is usually rejected for cases of strumous disease of the ankle or posterior tarsus on account of the liability to recurrence of the disease in the stump, and at first sight it might appear that WLADIMIROFF'S operation lies open to the same objection. But the cases are not quite parallel. In PIROGOFF'S amputation part of the os calcis is preserved, and this very bone may have been involved in the primary disease. In the latter operation the os calcis and astragalus are completely and wholly removed; these are the bones which are the most frequent seats of strumous and tubercular disease, and it is a common occurrence to see chronic destructive changes in them, or involving the ankle-joint, which disable but do not otherwise injure the anterior part of the foot. For suitable cases the operation is certainly worthy of being carefully tested. SKLEFASSOWSKY'S patient had shortening to the extent of one centimetre only, which is quite an insignificant amount.

Annotations.

"Ne quid nimis."

THE CASE OF DR. BRADLEY.

AT the last November assizes, David Bradley, M.D., formerly practising at Brimmington, Derbyshire, was convicted of having attempted to commit a rape upon Eliza Swetmore, the wife of a collier. The indictment included the more serious offence, but the jury found the prisoner guilty on the minor charge only. The prosecutrix, who admitted she had been the subject of epileptic fits since she was eleven years of age, and that her father had been confined in a lunatic asylum, deposed as follows:—She went to the surgery of the prisoner for some medicine, and whilst there he had carnal knowledge of her against her will, both whilst she was on two chairs, and again on the floor. She further stated that she resisted with all her might, and that she cried out, "Oh, doctor, don't." The latter assertion was corroborated by the housekeeper of the accused, and there seems no reason to doubt its accuracy. After the alleged rape she went immediately to the house of a neighbour, and complained of the assault. When Dr. Bradley was taxed with the offence, he said the prosecutrix had had a fit; at the same time he informed his housekeeper of the charge made against him. It transpired during the hearing before the magistrate that the surgery-door opened on to the street, and that the only indication of a struggle on the part of the deceased was that her neckerchief was off, and there was a small indentation on her neck. Dr. Palmer, who examined her the same evening, found no signs of the specific offence, but is said to have given it as his opinion that an epileptic fit would not be recovered from within half an hour, whereas the alleged assault did not occupy more than five minutes, after which the woman walked unaided out of the surgery. No evidence was forthcoming of injury or marks on Dr. Bradley's person or dress. The Lord Chief Justice, who tried the case, and concurred in the verdict, remarked, when charging the grand jury, that "the woman's statement was curious," but he seems to have been impressed with the calm and unbiased manner with which Mrs. Swetmore gave her evidence at the trial, and this he said was a great deal in her favour. He further dwelt on the fact that the counsel for the defence did not cross-examine the prosecutrix on her evidence-in-chief, as regards her statement that Dr. Bradley removed her hat when she went into the surgery, and let her leave the building when the proper thing—she being ill—was for her to remain in it. The last statement cuts both ways, for what would be more natural, if the crime had been committed, than that the accused should try to detain his victim in order to persuade her to consent to conceal his guilt. Again, with regard to the duration of an epileptic fit, every medical man knows that it may be momentary, or end only with the death of the subject. The removal of the woman's hat was the most likely thing to be done either by a doctor or a layman, as witness the daily treatment of fits in the streets. Assuming that a rape was neither committed nor attempted, what are the alternatives? Either the woman made the accusation *mala fide*, or she was impressed with the belief that she had been ravished, a belief albeit unfounded in fact. From a careful perusal of the depositions and a calm and deliberate investigation of the case in all its bearings, we are driven to the conclusion that the last hypothesis is the correct one. Persons of neurotic taint, especially those subject to perturbations of the feelings, and a general perversion of orderly innervation, such as is so often witnessed in epileptics, are liable to misinterpret their sensations in the direction of the one most prominent for the time being. If Mrs. Swetmore's evidence is to be relied upon, we fail to see the justice of

the verdict. She swore positively that Dr. Bradley effected his purpose both on the chairs and on the floor, and yet the jury acquitted him on the major count of the indictment, finding him guilty only of the attempt. The evidence is to our minds perfectly consistent with the innocence of the convict, and we doubt not that had the court been aided with independent expert testimony, Dr. Bradley would not now be undergoing two years' imprisonment with hard labour. We understand that a petition to the Home Secretary is in course of preparation.

REMUNERATION OF MEDICAL OFFICERS OF HEALTH.

SOME time since we drew attention to the attempt that was being made by the Rural Sanitary Authority of Chesterfield to reduce the salary which Dr. Angus Mackintosh received in his capacity of medical officer of health, and we expressed a hope that, under the circumstances of the able and indefatigable services which Dr. Mackintosh had so long rendered to the district, the proposal would be resisted by the central authority. Fortunately, the Local Government Board announced the withdrawal of repayment of half the salary if the authority persisted in their intention. Notwithstanding this, however, and under the impression that they only had to show a bold face, the authority made the appointment at a reduced salary; but when, later on, they found they had really lost repayment of £200 a year, they rescinded their resolution, and Dr. Mackintosh continues at the original salary. It is promised that a similar attempt will again be made in March next, and it is to be hoped that both the Local Government Board and the officer of health will be firm in resisting it. The action of the Board is limited by the Public Health Act. The Board can refuse repayment, but they cannot refuse sanction if a properly qualified officer himself accepts a reduced salary which the authority are prepared to pay entirely out of the rates.

A MAGISTRATE'S OPINION ON MADNESS.

A CASE which has just occurred at Dungarvan, in which a woman about whose insanity the local magistrates were not sure, although the doctor was, on being remanded to the workhouse, attacked the inmates indiscriminately, and placed her own child on the fire, with the effect of burning it dangerously, will serve, and doubtless be utilised, to illustrate the sort of opinions which may be generally expected from magistrates if they are empowered to act as censors of medical certificates. We have not a particle of faith in the efficacy of this sort of lunacy reform. We do not understand how any member of the profession can support it. It seems an insult to the general body of practitioners to suppose that their written judgments would acquire greater value in consequence of the authority acquired by a formal process of attestation before a justice of the peace. We would not stoop to such a proposal. It assumes that which we emphatically deny—namely, that there is need of some measure like this to guard against the *mala fides* of certifiers. No such need exists. The reform we desire, and the only reform we could willingly accept as sufficient, is such a change in the law as would relieve the profession of the entirely non-medical and strictly legal duty of drawing up and signing documents which are warrants for imprisonment, and at the same time legal instruments of social disqualification and personal disability and disgrace. Let who will assert the contrary, we affirm that anyone and everyone who has been certified to be of unsound mind is permanently damaged in his or her own eyes and in those of the community. This injury ought not to be inflicted for the mere sake of treating a case of brain disturbance called "insanity," when no one in his senses even dreams of doing the same wrong to the character of a fellow-subject when he chances to be affected with that often far more formidable brain disturbance which is called "delirium." Laymen, albeit they hold Her Majesty's Commission of the Peace, cannot possibly be competent to decide on the medical issue, Is or is not a particular person insane? As well ask the local representative of Beadledom to diagnose a case of valvular disease of the heart. The notion of trusting the magistracy with such a duty is preposterous, and ought to be scouted as itself madness.

THE WAGES OF THE WORKING CLASSES.

IT is satisfactory to be told by so good an authority as Professor Leone Levi that the earnings of the working classes amount to £521,000,000 per annum, or, exclusive of food &c., £470,000,000; yielding an average of 32*s.* per week per family, assuming each family to have 2·17 earners. Comparing the earnings of the working classes for the year 1867 with those of 1884, there is an increase from £38 to £42 14*s.* With good health and good thrift the case of our working classes should not be so bad as it is. We may well believe with Professor Levi that in no other country are the working classes so well off. The next most important question is, How are the wages spent? It is useless to maintain that the answer to this question is satisfactory. Part of the unthrift is to be lightly condemned, but much of it is really culpable. The enormous amount spent on drink is not denied by any authority. It is said that while we as a nation spend on bread £70,000,000, on milk £30,000,000, on butter and cheese £25,000,000, on house rent £70,000,000, and on the rent of farms £60,000,000, we spend on alcoholic liquors £136,000,000. We want improvements in cooking for the working classes, so as to make the most of their food supplies. This is to be done partly by educating girls more practically, and partly by public arrangements. There is one thing on which the working classes spend far too little, and on which they will, when they are wiser, spend much more—that is, on good medical attendance, not only on themselves, but on their wives and children. Nothing would more conduce to their happiness than better arrangements for their health. The working man is often tempted to say, "How cheaply can I get medical advice?" One day he will say, either individually or as member of a club, "On what honourable and reasonable terms can I get a good and experienced medical adviser to take a personal interest in the health of myself and family over an extended time?" Professor Levi's figures show that there is nothing in the economic condition of the working classes to justify the low remuneration of medical men in some clubs, and the great extent of gratuitous medical service.

POPLITEAL ANEURYSM SIMULATING SARCOMA.

PROFESSOR SHEPHERD, of McGill University, relates in the current number of the *American Journal of the Medical Sciences* the case of a man aged forty-six, who was treated in 1875 for double popliteal aneurysm by compression. Two years later the small lump which had remained in the right ham began to enlarge and pulsate, and was again "cured by compression." In the summer of 1882 he again noticed a small hard tumour in the right ham, which did not pulsate, but gradually enlarged. When he came under treatment in December, 1883, there was a large indolent ulcer in the lower and outer side of the leg, and a tumour nearly the size of a man's head on the back of the thigh, which was immovable, smooth, inelastic, without pulsation, fluctuation, bruit, or thrill, and which was in no way influenced by compression of the femoral artery above it. Coursing over the

tumour were large veins, but there was no œdema of the leg. The inguinal glands were enlarged. Amputation of the thigh was performed, and on examination of the tumour it proved to be a mass of fibrin, not deposited in laminæ. The mass was solid throughout. At the lower part of the tumour its capsule was found to be continuous with the external coat of the artery, and about this point the clot was in a softer condition than elsewhere. The difficulties of diagnosis presented by this case seem to have been insuperable. Except for the fact that the man was known to have had a popliteal aneurysm which had relapsed, there was nothing to point to the correct diagnosis. From the description of the case there is no doubt that the treatment was the best that could have been suggested. No milder measures offered any prospect of cure; to attempt to excise the aneurysm would have probably led to a fatal result; and considering the presence of the large indolent ulcer of the leg, and that the sciatic nerve was tightly stretched over the tumour and considerably flattened, it is obvious that amputation was called for.

INSURANCE AND CHILD MORTALITY.

A REMARKABLE statement was lately made by Dr. Ritchie of Leek, respecting the rise in infant mortality since the practice of insuring the lives of children in their first year was introduced there. As at first reported, the mortality prior to this period was 15 per 1000, and rose during it to 170. Further evidence has shown that there is a clerical error in these figures, and that the excess in the death-rate consists in the difference between 156 and 186 per 1000. This materially alters the aspect of the case. Still, the excess, though not absolutely so great, is decided, and, inasmuch as it is constant, calls for explanation. How much of it is due to so-called natural causes, such as prevalent disease, to accidents, to local changes affecting public health during the period of operation of the insurance system, and how much, if any, is to be laid directly at the door of the latter? Of course it is impossible for us or anyone to give a ready answer to this question. What is required is a prolonged investigation which will aim at ascertaining the various possible causes of illness and death which might be held accountable, and the various degrees of their action, during, before, and after the time in question. We must probably allow, however, that some such comparison has been drawn before a statement so pointed as Dr. Ritchie's has been publicly made. A medical officer of health is in the best position for knowing the results of all conditions ordinarily affecting health and illness in his district. The institution of a further inquiry is, however, very desirable for many reasons. Without wishing to blacken the reputation of human nature, we cannot but admit that there is ample evidence to show that infant life is less respected than it ought to be. It is a life which is only too easily taken, the means by which this may be criminally accomplished are many, their discovery at times is very difficult, and conviction for crimes of this nature is in many cases impossible. Neglect alone will take this life, errors of judgment in management can be turned into errors of purpose for its extinction. Thus, bread and biscuit have killed many children. They are among the "farm" foods of infancy. It would certainly be most unfair to conclude that the poor are naturally less affectionate towards their children than the wealthy. It is equally beyond question that unnatural parents are found, and not seldom in that class, as in all others. Moreover, poverty with its associations brings temptations and longings which well-conditioned people can hardly estimate. Then we must remember the many children born, one may say, without father or mother in the full sense—the illegitimate class. Charity, public or parental, is not always careful to preserve these amongst us. They become the charge of underpaid nurses, and are too often brought up anyhow. Their living is rather permitted than desired. With these facts before us, the placing of a premium of several pounds on the life of an infant is clearly a measure which, however desirable in suitable cases, requires at least a shrewd supervision in its working in order that it may not become an incentive to crime in the ill-disposed.

HOSPITAL FOR INFECTIOUS DISEASES IN LIVERPOOL.

THE City Council at a recent meeting decided to apply to the Medical Institution for the opinion of the members as to the number of beds which should be provided in the new permanent hospital for infectious diseases. A special meeting of the institution was held on Tuesday, the 13th inst., when a report in substance as follows was adopted:—

"The institution, after a careful consideration of the subject, are of opinion that, if due regard be had to the size of the hospital wards, the necessities of non-epidemic years will be met by the provision of permanent accommodation for 300 patients suffering from infectious diseases other than small-pox. As to epidemic years, they are of opinion that the permanent hospital or hospitals, if it should be decided to build more than one, should be placed on a space of ground sufficiently large to admit of a rapid and economical extension of the accommodation by means of temporary sheds or such other structures as experience has shown to be efficient. With reference to small-pox, they are of opinion that, under rigidly enforced rules as to separate nursing and the visits of patients' friends, permanent provision might be made for forty cases in a building erected on the grounds of the fever hospital, but entirely dissociated from it, without risk either to the inmates of the fever hospital itself or to the inhabitants of the surrounding district. But for epidemic times it would be necessary, in case the tenancy of the Park Hill Estate should at any time be determined, that a large and sufficiently isolated space should be acquired, and that all but the severer cases should be conveyed to wards erected on it, the beds provided near the fever hospital or hospitals being reserved for those patients who should be deemed too ill to bear a more prolonged journey."

THE CULTIVATION OF SUGAR BEETS IN ENGLAND.

FOR many years past experiments have from time to time been made in England and Ireland on the cultivation of the sugar beet. In the present depressed condition of agriculture these experiments are of the highest importance, and we are glad to find that they appear to have been successful. We have received from Messrs. Bolton and Partners (Limited), of Westminster, a proof of the report of Professor Church on the results of the cultivation during the past year. This report, which carries great weight from the known integrity and high scientific fame of its author, represents the prospects of the industry in a very hopeful light. It appears easy with good management to get crops of fourteen tons to the acre of small beets, containing 14 per cent. of sugar. Such crops will, it is said, pay better than wheat, and that an extensive cultivation is possible is proved by the fact that we now pay £10,000,000 a year for foreign sugar. Professor Church believes, indeed, that as much as thirty tons per acre might be obtained in good years by close planting and with due care and sufficient manure. Of course it may be said that the hot summer of 1884 was the cause of the success, but the opinion of Professor Church is quite against this view; he regards the late crops as "by no means offering a series of exceptionally well-grown and rich roots." With the strontia process, which has of late been so largely adopted

in sugar manufacture, the free use of manures is possible, and will of course increase the crops. The report abounds with sound advice as to the management of the land and the crops, and we cannot but hope that the new industry may be a real help to the sore distressed British farmer. Any surplus roots may be used as cattle food, since, although lighter, they possess a higher nutritive value than mangolds.

A NEW PATHOLOGICAL SERIAL.

THE first part of a new publication devoted to pathology, and doubtless intended to be issued at intervals, like the volume which Professor Stricker sends out from Vienna, has just appeared (*Beiträge zur pathologischen Anatomie und Physiologie*, Erstes Heft. Jena: G. Fischer). It is edited by Professor Ziegler and his assistant at Tübingen, Dr. C. Nauwerck. This part opens with some contributions to the pathology of Bright's disease by the last-named writer, the portion of the monograph here published dealing in turn with the pathogenesis of Bright's disease, with Bright's disease in croupous pneumonia, with acute glomerulo-nephritis and acute nephritis in opium poisoning, and is in the main a histological study in which the views of other writers are freely criticised. A paper on the histogenesis of periosteal callus by Dr. E. Krafft follows, and one on the Biology of Mucor Corymbifer, by Armand Hückel. Dr. Mögling contributes the first portion of a monograph on the formation of the Hæmorrhagic Infarction, which is mainly devoted to a historical survey of the question of embolism, preliminary to the relation of the author's own studies on the subject. The appearance of this serial, which occupies ground already filled by Virchow's *Archiv*, shows how fertile is the field of pathological inquiry in Germany, and adds to our regret that as yet no similar publication has appeared in this country.

COCAINE IN DENTAL SURGERY.

WHEN cocaine was first introduced, both dental surgeons and their patients were very sanguine as to its value in reducing the excessive painfulness of operations in dentistry, and they hoped it could be used for allaying the sensitiveness of dentine when the caries was being excavated previous to "filling" the cavity. They also hoped it might be found useful to relieve the pain attending extraction of teeth and roots. The subject was introduced at the December meeting of the Odontological Society by Mr. Oakley Coles and Mr. S. J. Hutchinson; but their experience and that of the members present who joined in the discussion did not seem to point to any tangible results as to the effects of this drug. Most of those present agreed that in the 4 per cent. solution the action was almost inert on dentine, though it would relieve the sensitiveness of an exposed "pulp." Since then various experiments have been made with a 20 per cent. solution and with the hydrochlorate of cocaine in its crystalline form. The latter seems in a certain number of cases to produce a distinct abatement of *pain*, although *sensation* remains. It has been applied for the painless extraction of roots by damping a small piece of amadou, in size less than a pea, then dipping it in the crystals, painting the neck of the tooth and the gum around, and letting the crystals dissolve in the natural secretion, keeping away an excess of saliva with pads of lint or amadou. This has been found in a few minutes to deaden sensation sufficiently for the elevator and forceps to be used without much pain, although the patient was conscious of the sensation of the operation. More experience in the use of the drug, however, is required to warrant the conclusion that this concentrated application can safely be made without causing subsequent inflammation or sloughing. No record of its employment by submucous injection has come under our notice. It is possible that injecting a 4 per cent. solution on each side of the tooth to be extracted may produce sufficient local anæsthesia. This operation, however, has its drawbacks, as the very insertion of the needle would be dreaded almost as much as the extraction itself. In excavating the caries from a very sensitive tooth the 20 per cent. solution has produced very varying results, in some cases allaying the tenderness, in others without effect. It has also been used for capping exposed nerve-pulps, as it is known to be antiseptic as well as anæsthetic. The *Dental Cosmos* for December contains the experiences of one or two well-known operators in America, who had found marked relief to result in very sensitive cavities by the use of cocaine, and they point out that the cavities should be made quite dry, then the cocaine applied for a few minutes and the cavity again dried, when the sensitiveness seemed to be much lessened. It had also been found useful for deadening the excessive sensibility of the contents of root canals when clearing them of the remains of the nerve pulp. One of these gentlemen reports his successes and failures to be about equal. As a general result, from these and other experiments, it may be concluded that cocaine is without doubt of much value in dental surgery, but the complete *rationale* of its most successful use is as yet undecided. Mr. Brunton of Leeds recommends the citrate of cocaine in a pasty condition for allaying the sensitiveness of dentine.

SELOUS v. THE WIMBLEDON AND CROYDON SANITARY AUTHORITIES.

THIS case, in which the plaintiff, as the reversioner of a residence known as Garratt House, claimed damages and an injunction against the Wimbledon urban and the Croydon rural sanitary authorities for proceedings in connexion with their sewage farms, has occupied Mr. Justice Denman for a considerable time. The judge took the case without a jury, and having himself visited the premises in question, he last week delivered judgment. On the plaintiff's property is a piece of water known as the Western Pool, which is connected with the river Wandle. The Wimbledon local board have their sewage farm close by, and a part of it consists of a field known as the Willow-mead, adjoining the Western Pool. The plaintiff complained of nuisance from the sewage farm operations, and also of the eddying back of their sewage effluent into his pool. The Croydon authority, he further complained, discharged some of their effluent directly into the Western Pool, the amount varying, but it carried with it on an average more than a ton of foreign matter a week. A camp shedding had also been erected on the plaintiff's property, to carry an effluent pipe into his pool. Mr. Justice Denman, after bearing testimony to the recent efforts made by the Wimbledon Local Board to carry on their arrangements for sewage disposal in a satisfactory manner, decided that they had no right to erect the camp shedding, and must pay damages and remove it; and that the plaintiff was further entitled to damages for the manner in which the sewage had been disposed of on the Willow-mead and for the contamination of his pool. The nuisance on the latter head was, however, nominal, and the judge stated that if the effluent from the Wimbledon farm was maintained at the standard reached on the day of inspection, the authority would, in his opinion, comply with the order the Court was about to make. As regards Croydon, it was decided that the authority had no right to place the mouth of their effluent pipe in the Western Pool, and the judge further expressed an opinion that the Legislature had not authorised local authorities to carry water upon the premises or land of a private owner. In this case, however and quite apart from any such authorisation, the effluent was so impure that sewage fungus was discharged from the

pipe into the pool, and, unless the arrangements were soon altered, the present damages of £200 would be liable to be increased. The case is one of importance in the interests of the public, for local authorities, having the public rates to fall back upon, are but too apt to interfere in this matter of sewage disposal with private rights; and it is not often that the aggrieved party can afford to command the assistance of a court of law.

THE TRADE IN CHOLERA GERMS.

WE are not surprised to find a lay contemporary "poking fun" at the new trade which has sprung up in bacilli &c. for microscopic purposes. It is necessary that these organisms, which are alleged to be the "germs" of disease, should be brought under the notice of the profession, and the purveyors of "specimens" must of course be the agents in their distribution; but we confess that it can scarcely strike the uninitiated mind as decent, or even safe, to allow the seeds of a dreaded malady to be handed about, with all the risks of breakage and dissemination, and without precaution. The facts that accident is extremely improbable, and that even if these bacilli were introduced into a living organism they would not be likely to propagate the disease after the treatment they have received, are not of a nature to relieve such anxiety as the banter of our contemporary may have awakened. There ought to be an authoritative statement on the subject by those who traffic in these "germs," as well as by scientific investigators who use them for study or experiment.

"SYMPATHY" BETWEEN TWINS.

IF two projectiles of similar construction and properties are thrown from the same gun simultaneously, they are not unlikely to travel in lines closely parallel. We do not speak of "sympathy between" these two objects. The facts that they are themselves alike, and that they have been similarly conditioned, are held to account for the accord they show in behaviour. Doubtless much of the so-called "sympathy" between twins is to be explained on this principle. Every now and again we hear marvellous stories of twins suffering together and dying together. Much of the parallelism is probably made up of incidents "remembered," and which did not strike the narrators until after the climax had been reached in some striking community of action or suffering. When we come to sift the chaff from the wheat in these stories, there is little left which cannot be explained on the grounds of similarity of nature and circumstance.

A PREMIUM ON DISEASE.

THE French Government Commission on Unwholesome Buildings has issued a report concerning the condition of the Rue Ste. Marguérite, where the cholera broke out among the rag-pickers who frequent this neighbourhood. In the forty-seven houses of this street there were forty-five deaths at the last epidemic; but, after all, diphtheria, typhoid, and small-pox are more fatal than the occasional visit of cholera. The death-rate for this quarter of Paris is estimated at 40·2, whilst the average of the city is put down at 28·1, and that of the aristocratic seventh arrondissement at only 16 per 10,000 of the population. The death-rate of the Rue Ste. Marguérite, though inferior in figures to certain English slums, is very high when we consider that there is a far smaller proportion of children among the French rag-pickers. The Commission further states "that the number of conscription is below that of five-sixths of the Paris arrondissements, and that the recruits are notoriously inferior in stature, a fact which proves they are exposed permanently to morbid influences." The remedy suggested will not, however, tend to abolish such nuisances. It is proposed that the proprietors should be expropriated and a large number of the houses pulled down. The latter part of the proposal must be cordially approved; but expropriation would mean the payment of heavy and unmerited compensation to proprietors who, by neglecting their duty, have caused the premature death of a great number of people; it would be placing a premium on unwholesome dwellings. Unscrupulous speculators would court expropriation by converting their property into a centre of disease.

STRICTURE OF THE RECTUM AS A CAUSE OF PROLAPSUS.

IN the January issue of the *Revue de Chirurgie* Dr. Eug. Bœckel relates the cases of three children brought to him for troublesome prolapsus of the rectum, in whom he found the summit of the protrusion to be formed by a narrowing of the intestine. In each case the dilatation of the stricture was followed by a speedy cure of the prolapse. Dr. Bœckel asserts that if looked for it will be found that the majority of cases of prolapsus recti in young children are caused by congenital strictures of the upper extremity of the rectum. He states, also, that the conical shape of the protrusion and the extreme narrowness of the orifice at its end are the diagnostic features of this form of prolapsus. The treatment recommended is the wearing of a tubular pessary to dilate and hold in place the stricture, while allowing flatus and liquid fæcal matter to escape. We are unable to accept altogether these views. If stricture is such a frequent cause of prolapse, it is a remarkable fact that so many cases have been cured by methods of treatment which cannot have removed such a cause, and we are by no means satisfied from the account given that Dr. Bœckel's pessaries actually dilated any stricture in the cases he records. The narrow orifice of the protrusion was probably due to the traction upon the part and to the constriction to which it was exposed in its unnatural position. Further, Dr. Bœckel is certainly in error in attributing a stricture at the junction of the sigmoid flexure and rectum to a defect in the union of the intestinal and anal portions of the alimentary canal. The anal infolding only forms quite the lower extremity of the gut.

THE PIGMENTS OF THE SUPRARENALS.

A VALUABLE and interesting communication was recently made to the Physiological Society by Dr. MacMunn, "On Myohæmatin, an Intrinsic Muscle Pigment of Vertebrates and Invertebrates; on Histohæmatin, and on the Spectrum of the Suprarenal Bodies." Physiologists have accepted Kühne's statement that muscle owes its colour to hæmoglobin, but Dr. McMunn contends that though the greatest number of voluntary muscles do owe their colour to it, yet it is accompanied in most cases and sometimes replaced by myohæmatin, whilst in other cases it entirely replaces myohæmatin. The cardiac muscle of every vertebrate animal examined by Dr. McMunn yields myohæmatin, which gives a very beautifully defined spectrum, totally distinct from any product of decomposition of hæmoglobin—e.g., methæmoglobin, acid, or alkaline hæmatin or hæmatoporphyrin. In order to demonstrate the spectrum of myohæmatin no reagent whatever is required. The spectrum consists of three bands, two of which persist after the bands caused by hæmoglobin have disappeared. The bands have been missed by other observers, simply because the presence of well-marked bands due to oxyhæmoglobin hides those caused by the presence of myohæmatin. The first band of myohæmatin occurs just before D, the next two are narrow, and placed between D and E, and two other faint bands may be present near the violet. Dr. McMunn has found myohæmatin in the cardiac muscle and some voluntary

muscles of many mammals, birds, reptiles, amphibians, and fishes. This colouring matter has also been detected in many invertebrate animals; indeed, it was first discovered in them. The substance is said to have been separated by digesting muscle in a pepsin solution, but it was slightly changed in the process; it was also obtained from the frozen myocardium of the rabbit by pressing out the plasma. Histohæmatin is a name given by the author to a class of pigments of wide distribution in the animal kingdom. Myohæmatin belongs to this class of pigment. The histohæmatins are believed to be respiratory pigments, for they can be oxidised and reduced in the solid organs, where they are found. Their absorption bands occupy almost the same place as those of myohæmatin. In the suprarenal capsules of many mammals the medullary substance gives the spectrum of hæmochromogen, while the cortex shows that of a histohæmatin. Wherever hæmochromogen is found it is probably excretory, and Dr. McMunn has only met with it in the liver and in bile, so that it must be regarded as excretory in the adrenals. It may be that the function of the adrenals is in part to metamorphose effete hæmoglobin or hæmatin into hæmochromogen. Disease of or removal of the organs, as in Tizzoni's experiments (*vide* THE LANCET, vol. ii., 1884, p. 549) prevents the removal of the pigment; hence pigmentation of the skin and mucous membranes sets in. Vulpian has shown that taurocholic acid is present in the medulla of the adrenals, of which the structure is like that of the liver; the presence of large lymphatics, together with the consideration of the facts of structure and of the well-known results of disease of these organs, tends to prove that an active metabolism takes place in them, and Dr. McMunn believes that he is justified in concluding that these organs have a share in the downward metamorphosis of effete colouring matter.

MENSTRUATION IN AN INFANT.

Il Morgagni (10th inst.) relates the case of an infant girl, who, when barely four months old, commenced to menstruate regularly. Dr. V. Derveer, who had ample opportunity of studying the case when the child was two years and seven months old, reports that she then weighed forty pounds. She had the facial expression and physical conformation of a girl from ten to twelve years of age. The mammæ were of the size of small oranges, the mons veneris well developed and covered with hair, the labia majora and other parts of the vulva fairly developed. The child was very intelligent, but of an irritable temperament, which was especially marked at the approach of the catamenial period. These recurred as a rule every four weeks and lasted four or five days, but at one time were interrupted for three months. The child was then exceedingly irritable and had sleepless nights, but perfect health was restored so soon as the menstrual regularity was re-established.

A BREECH-PIN IN THE BRAIN.

AN interesting case of recovery after severe injury to the brain is recorded by Dr. Kemper in the *American Journal of the Medical Sciences* for January, 1885. A youth, eighteen years of age, while out shooting, had his gun burst, and a piece of metal, an inch and a half long and weighing 617 grains, entered his brain through the forehead. The accident happened half a mile from his home, and the lad was alone. He was insensible for a time, but four hours later he walked home unaided, and in possession of all his mental faculties. Next day, twenty-one hours after the injury, Dr. Kemper saw the lad, and found him quite sensible, with a pulse of 64 and a temperature of 104·7°. There was a curved wound an inch and a half long vertically above the right eyebrow, through which the finger passed into the skull and on into the brain, where a hard substance was felt and subsequently withdrawn by forceps, which proved to be the breech-pin of the gun described above. A few small pieces of bone and of a felt hat were afterwards removed. Water-dressings were applied, and the youth made an excellent recovery. The depressed cicatrix pulsates, but is not tender to pressure; vision is perfect, and the only ill-effect observed is that the lad "felt the heat" during the summer.

AN EL DORADO FOR MEDICAL MEN!

WE do not wish to tempt Sir Spencer Wells or any other of our distinguished gynæcologists to leave our shores, but we cannot withhold from our readers some account of a country where the medical and surgical arts seem to be appraised at something more like their proper value than with us. We are borrowing from the letter of a correspondent in the *South American Journal*, giving an account of the general charges for medical service in the Argentine Republic. The charge for a consultation at the doctor's house is 8*s*., for a visit 16*s*., for a confinement £20. For special operations by good men, but not stars of the first magnitude, the following charges are stated to be paid without demur: –

"For extraction of ovarian tumour	£1200
Amputation of arm, principal	600
„ „ two assistants, each ...	400
Delivery with operation	400
Attendance during typhoid fever	200
Visit by a physician for dropsy	50

Consultation fees, £20 and upwards."

Not only is it possible to make money in the Argentine Republic, but it is easy to invest it properly. The climate is of great variety over a territory extending from the tropics to Cape Horn. In order to practise, an examination must be passed and a licence obtained from the Government Medical Board. This examination is conducted in the Spanish language, which must be mastered by the candidate. But this is no great hardship, considering how fine a language it is and how great would be the reward of reading "Don Quixote" in the original—the one book which Sydenham recommended to Sir Richard Blackmore. The correspondent signs himself "Honorarium," and will be glad to answer any inquiries addressed to him through the journal in which he writes.

THE HABITUAL DRUNKARDS ACT.

WE regret to see that Mr. Paget, the stipendiary magistrate for Hammersmith, seems to have raised an unnecessary difficulty in the way of an unfortunate lady, an habitual drunkard, getting into a home registered under the Act for dealing with such cases. Everybody knows the miserable weakness and inadequency of this piece of legislation, the consequence of which is that hundreds of habitual drunkards are going to wreck and ruin, and carrying their families with them. The weakness we refer to is, of course, that part of the Act which requires the consent of the drunkard, who is generally incapable of such an unselfish and enlightened act. But Mr. Paget had not this difficulty to encounter. The lady was quite willing—to her credit be it spoken—and she was most kindly assisted by two clergymen, who took much trouble to get the necessary authorisation and to make all the arrangements. Thereupon Mr. Paget objected to sanction the removal—or, as he saw fit to describe a legal and beneficent proceeding, "the imprisonment"—on the ground that the retreat to which the patient was to be sent was not in the county in which he had jurisdiction. There is nothing, so far as we know, in the Act which requires the consenting magistrate to be in the same county as the retreat; and it is surely intolerable for any magistrate

to raise a prejudice against treatment in a retreat by calling it imprisonment. Mr. Paget's action in this matter requires further attention, and we hope will receive it. Meantime, we are glad to learn that the patient has been safely removed to Colman House Retreat, Worcestershire, the only licensed retreat exclusively for the reception of ladies.

PROSELYTISING IN HOSPITALS.

IT is much to be regretted that those who cherish earnest views on the subject of religion should so generally regard hospitals as fit places for the propagation of their special faiths. We have no desire to make any particular reference in these remarks. Suffice it to say that there is need of greater consideration in many quarters which should be free from censure or even suspicion in this respect. Hospitals and infirmaries are homes of cure for the sick, not places of repentance, retreats for the careless or distressed in mind. It is desirable that chaplains should be appointed to officiate at the institutions, but their ministrations ought to be entirely free from a sectarian character. We do not want Catholicism, either Roman or Anglican, or Protestantism or Evangelicism, or Nonconformity or Calvinism, or any one of the hundred specialties of religious faith and doctrine, forced upon the sick in the hour of their weakness and impressibility. It is strange that those who lay stress on the essential quality of sincerity in matters of religion should desire, or even accept, the sort of "change" wrought by the persuasive influence of chaplains and "sisters" at a time when the subjects of this influence are obviously not in a condition to know their own minds, much less to form persistent judgments. When we hear of patients being "converted" to and inducted into new faiths while in hospital, we scarcely know which most to deprecate—the zeal without discretion of the proselytisers, or the gullability of the proselytes.

REPORT ON SANITARY MEASURES IN INDIA.

THIS report, in which are briefly described all the sanitary measures adopted in India during the year 1882-83, is arranged under seven heads—viz., European army, native army, general population, gaols, vaccination, medical institutions, and sanitation. The statements regarding the health of both European and native trooops are exceedingly satisfactory, and the marked improvement which has taken place is naturally attributed by the Army Sanitary Commission "to the effect of sanitary improvements at military stations, and to generally improved management." Respecting the general population, it is stated that, during the year under review, 4,757,024 persons died in India. The progress recorded from all parts in the adoption of vaccination is most gratifying, and nowhere does there appear to have been offered any persistent opposition on the part of the native population to its performance. The number of deaths from small-pox in Bengal shows a falling off of more than 10,000. In the concluding pages of the report the different measures of sanitation carried out or sanctioned are passed in review, from improvements in Calcutta to works executed in military barracks and cantonments.

MEDICAL EDUCATION IN THE UNITED STATES.

THE *Chicago Morning News*, in commenting on a recent article in our columns on the Mushroom-like Growth of Medical Schools in the United States, does not seriously invalidate our representation, but tries to show that, as regards the State of Illinois, the effect of an Act to regulate the Practice of Medicine has been greatly to reduce the number of unqualified persons in the State. The *Morning News* further admits that in December, 1884, 116 Institutes of all classes in the States were entitled to grant degrees and diplomas. In Illinois, indeed, the State Board now requires all entrants to the profession to pass a preliminary examination; but this only covers the subject of reading and writing, so as to exclude such a gentleman as is described as "A Nachural Practishuner," or that other who had practised ten years under "the supervshen of a pereseptor and attended to ful corses of instructions, at —— colag." Illinois has been followed in this step, we are told, by 102 other Institutions; but the step so modestly described by our contemporary is not a very long one, and leaves much to be desired. He admits that in 1880 there were not half a dozen Colleges in the country which instituted any sort of preliminary examination.

THE LATE SURGEON C. B. LEWIS, ARMY MEDICAL DEPARTMENT.

A BRASS to the memory of this promising young officer has recently been placed in the chapel of the Royal Victoria Hospital at Netley. Surgeon Lewis entered the service about six years since, and died of cholera at El Warden, while serving with the army of occupation in Egypt, on July 30th, 1883, at the early age of twenty-nine. During his student days at King's College, Lewis was universally popular, and was well known as an athlete, having won the Mile Challenge Cup in the United Hospital Athletic Sports for several years in succession. The memorial brass has been erected by several of his brother officers and old friends in both the Indian Medical Service and Army Medical Department, and has been well executed by Messrs. Clayton and Bell of Regent-street.

THE SECOND REPORT OF THE SPECIAL CHOLERA COMMISION IN INDIA.

THE supplement of the official Gazette of India just received contains an important communication from Dr. E. Klein to the Sanitary Commissioner with the Government in India, in continuation of the memorandum published a short time ago by the Special Cholera Commission in India. In the report, which we hope to publish *in extenso* next week, the statement is made that comma bacilli have been found in tanks without any case of cholera having occurred among the large number of people using them.

MICRO-BIOLOGY.

THE last published number of the *Barcelona Review of the Medical Sciences* contains an elaborate article by Dr. Carreras-Solà on the relations of microbes to diseases ("Los Microbios en sus Relaciones con las Enfermedades,") and one by Dr. Ferrano on the parasite of cholera. Both contributions are illustrated by elaborate lithographic plates, in which the bacilli of different diseases are represented with so much distinctness as pictorially to surprise investigators who know how difficult it is to differentiate, under the microscope, between the varieties of pathological microbes.

DIPHTHERIA AT WATFORD.

DIPHTHERIA, which is by no means a common disease in Watford, was exceptionally prevalent at the close of last year, and it appears to have been mainly spread through the agency of elementary school attendance. The disease has since abated. Disinfection of schools during the Christmas holidays has been carried out; and now that the reassembling of children has taken place, it will be well to follow out the principles which have been laid down on this subject by the memorandum as to infectious diseases and school attendance issued by the Local Government Board.

THE CLINICAL SOCIETY.

THROUGH the loss of a portion of the manuscript the annotation headed as above in our last week's issue failed to mention the vote of thanks so warmly accorded to Dr. Sidney Coupland on the proposal of Mr. W. Haward, seconded by Dr. J. Anderson. Mr. R. W. Parker responded for the vote of thanks proposed by Dr. Semon, and Dr. Fowler for that to the other retiring officers of Council.

SMALL-POX HOSPITALS.

THE discussion on the question whether small-pox hospitals are necessarily a source of danger to the surrounding neighbourhood will be continued at the Society of Medical Officers of Health, 1, Adam-street, Adelphi, on Monday, January 26th, at 7.30 P.M.

THE death is announced of Professor Benjamin Silliman, the distinguished American physicist. He was joint editor of the *American Journal of Science* from 1838 to 1854, and since the latter date had been associated with Professor J. D. Dana as editor and proprietor. Deceased was Professor of Medical Chemistry and Toxicology in the University of Louisville, Kentucky, from 1849 to 1854, and in the latter year succeeded his father as Professor of General and Applied Chemistry in Yale College.

DR. G. H. BALLERAY of New Jersey reports a case of strangulated hernia in a man aged eighty, who was suffering from an attack of facial erysipelas. Herniotomy with opening of the sac was performed, and the man recovered, the wound healing well, "the reparative process being apparently unaffected by the existence of the facial erysipelas." The operation was performed with strict Listerian precautions.

MESSRS. BAILLIÈRE, TINDALL, & COX announce the publication of a new periodical devoted exclusively to surgery, called *Annals of Surgery*. It is to be an international monthly review, edited in America by Dr. L. S. Pilcher of Brooklyn, and in this country by Mr. C. B. Keetley. In addition to original memoirs, editorial articles, and reviews, considerable space will be devoted to an Index of Surgical Progress.

IN a lecture delivered on the 16th inst. at the Royal Institution before a crowded audience on the subject of Living Contagia, Professor Tyndall dealt at length with the researches of Pasteur in connexion with the germ theory of disease, and declared that recent discoveries respecting hydrophobia and splenic fever showed that experiments with animals were turned to very profitable account.

M. TOULOUZE describes in the *Union Médicale* some old surgical instruments recently found during some excavations on the site of an old Roman road in the Rue Clovis in Paris. He believes that they date back to the period of Galen. They consist of an epilation forceps, a probe, and an ear-scoop — at least these are the uses for which M. Toulouze regards them as applicable.

SIR WILLIAM MUIR, K.C.S.I., LL.D., D.C.L., was on the 20th inst. unanimously chosen by the curators of the University to succeed Sir Alexander Grant in the Principalship of Edinburgh University.

PROFESSOR A. R. SIMPSON and Dr. BERRY HART have withdrawn from the Gynæcological Society.

THE Abbott-Downing Company, of Concord, make a horse ambulance which is well adapted for the excellent ambulance service of the American cities. It is a four-wheeled conveyance which is fitted up with every requisite and can be confidently recommended to firms and institutions in this country who need such a conveyance.

THE death is announced of Professor Friedrich von Stein, who held the chair of Zoology at Prague for more than thirty years. His chief work, published in 1854, was on the Development of the Infusoria. Professor von Stein was a distinguished pupil of Johannes Müller.

IN consequence of the prevalence of small-pox in Newington, the guardians of the St. Saviour's Union on the 15th inst. issued an order prohibiting the admission of visitors to the inmates of the Newington Infirmary, except in urgent and dangerous cases.

NEWS from the Mediterranean Squadron announces the death in Bighi Hospital, from typhoid fever, of Mr. Anthony Lynch, Surgeon, R.N. It is also stated that the mortality amongst medical men at Malta has lately been very heavy.

THE Local Government Board are stated to be about to hold an inquiry into the management of the small-pox camps and other institutions under the control of the Metropolitan Asylums Board.

MRS. MARSHALL HALL, the widow of the great physiologist, died on the 14th inst. at the house of her nephew, Dr. Marshall Hall Higginbottom, Nottingham, aged eighty-three.

RECENT advices from Alexandria announce that Dr. Sandwith has resigned his post as Director of the Board of Health at Cairo.

WE regret to see the name of Surgeon Magill, M.D., in the list of officers severely wounded at the battle of Abu Klea.

CANTOR LECTURES.

BY G. V. POORE, M.D., F.R.C.P.

ON CLIMATE IN ITS RELATION TO HEALTH.

AT the first lecture on Monday, Jan. 12th, delivered at the Society of Arts, Dr. Poore dealt mainly with those facts in regard to climate which are a necessary preliminary to any adequate discussion of the subject. Commencing with the chemical composition of the air, he pointed out that although its uniformity was not absolute, it was very nearly so — so nearly that it was exceedingly improbable that any variation in the chemical composition of the air could have any effect on the health of localities. He spoke only of the "open air," and left crowded dwellings out of consideration. Thus, the normal amount of oxygen in the air was usually given as 20·96 per cent. by volume, and the extreme figures given by Angus Smith were 20·86 per cent. in the East-end of London, and 21·00 per cent. on the northern heights of London. These variations were very trifling when compared with the variations in the absolute quantity of oxygen taken into the lungs under different conditions of pressure and temperature. Thus, of two men, one breathing air at a temperature of 32° F., and the other breathing air at a temperature of 80°, the former would get 192·6 grains of oxygen per hour more than the latter; and of two men, the one breathing air at sea level and

the other breathing on a mountain 5000 feet high, the former would get 361·88 grains per hour more oxygen than the latter, and yet the man on the mountain would probably be the more robust of the two. In the same way the variations in the amount of carbonic acid were too trifling to affect the health of a community. If oxygen were persistently deficient and carbonic acid persistently in excess, we had to inquire why, and the cause would be found to be due to combustion, respiration, and putrefaction, the last being a great cause of disease. The causes of the varying amounts of moisture in the air were next dealt with, and the causes of its deposition in the form of dew, fog, and rain. The uses of moisture in shielding us from the sun, and in checking radiation and thus preventing sudden alternations of temperature, and the warming effects of rain, were explained, and the conclusion was arrived at that although the moisture in the air affected our sense of well-being and comfort, and more especially of invalids, yet the amount of moisture, be it great or small, had *per se* little or no effect on the health of a community.

In so far as moisture favoured putrefaction, it had a very important indirect influence on health; and when warmth and moisture coincided, putrefaction of all kinds was apt to run riot, and zymotic disease was very prone to spread.

So with regard to temperature. It was an acknowledged fact that the power possessed by the human body of withstanding the extremes of heat and cold was, in so far as climatic temperature is concerned, unlimited. The only trouble due to excess of temperature was sunstroke and heat apoplexy, and even these were often due to errors of hygiene, dress, and diet more than to the heat. As for extremes of cold, ample food and ample clothing were all that was necessary to enable a healthy man to withstand them. The history of the twenty-five men belonging to the *Eira*, who, after ten months spent in a hut on Franz Josef Land, were picked up in robust health, afforded ample proof that food and protection enabled a man to keep well in sixty-five degrees of frost, and that the mere breathing of air having a very low temperature for months together was not harmful even when combined with deprivation of light and a state of crowding in the hut which in this, or still more in warmer latitudes, must have proved fatal to many of them. The wise precautions of Mr. Leigh Smith and Dr. Neale enabled these men to pass through an arctic winter unscathed.

At the second lecture on Monday, Jan. 19th, Dr. Poore began by calling attention to the rude health enjoyed by the crew of the *Eira* in the arctic regions, under conditions of which overcrowding and dirt were the chief characteristics. In answer to the question why conditions were harmless at the Pole which would certainly be harmful or even fatal at the tropics, he offered the explanation that at the Pole putrefactive and allied processes were impossible, owing to the fact that in the cold, dry arctic regions it was impossible for the bacteria, upon which putrefaction depends, to manifest any vitality.

Although he had ventured to assert that the extremes of heat and cold were not necessarily great producers of disease, a glance at one of the diagrams on the wall offered an apparent contradiction to this assertion, for from it they would learn that the deaths from respiratory disease increased in cold weather and the deaths from diarrhœa steadily increased in hot weather. There was a distinction to be drawn between a cause of disease and a cause of death. Cold weather was undoubtedly very fatal to persons with lung disease, disease contracted by overcrowding, intemperance, and filthy surroundings. The starved and the aged were very prone also to die from a congestive pneumonia. During cold weather also overcrowding in dwellings reached its greatest height. Cold was therefore to be considered as very prejudicial to persons with lung disease, but it could only be reckoned as an indirect and secondary cause of those diseases. Again, the heat was not the cause of the diarrhœa. It was only an indirect cause *vid* sour milk, putrid food, rotten fruit and emanations from putrefying sewers into the air or drinking water. A glance at the chief tropical diseases would show how many of them were connected with the putrefaction and decay of organic matter. Malaria, yellow fever, and cholera were all instances of this. Now, putrefactive and allied changes had been shown by Pasteur to be dependent on micro-organisms, which were found in the air, the soil, and the water. The study of these micro-organisms had become a study of prime importance, more especially as not a few of the zymotic diseases had been proved to be closely dependent upon them.

In considering the atmosphere as a cause of disease, nothing was of greater importance than a study of the floating matter in it. This line of research was being methodically carried out in Berlin and Paris, and the facts brought forward that night were mainly those furnished by Dr. Miquel, of the Observatory of Montsouris, in Paris. That solid particles could be carried hundreds of miles by the air was well known, for dust had been known to fall on ships at sea which must have been blown from African deserts 600 or 800 miles away. The labours of Ehrenberg, of Blackley (who directed attention to the large amount of pollen in the air), and of Maddox (who had discovered great varieties of fungoid spores in the air), were alluded to. Experiments conducted by Miquel at Montsouris had shown that in the years 1879-82 there were on an average from twelve to fifteen fungoid spores in each litre of air, and that these spores were more plentiful in hot than in cold weather. In addition to spores and pollen, the other matters found in the air and readily distinguishable by the microscope are mineral particles, particles of clothing, starch grains, and occasionally unicellular plants and ova of infusoria. The researches carried out by Miquel on the numbers of bacteria in the air have been most laborious. His method has been to draw through a large number of tubes of a special pattern and partially filled with sterilised bouillon a measured quantity of air, and to preserve the tubes a sufficient length of time to ascertain whether any bacterial growth had taken place. Thus M. Miquel would distribute 100 litres of air through fifty tubes, and if after due lapse of time ten of these tubes manifested bacterial growth and the remaining forty continued sterile, he would be sure that there were at least ten bacteria in the portion of air examined. This work has been done day after day, and often many times a day, by Miquel and his assistants, and we cannot too highly appreciate their great devotion and enthusiasm. Miquel has found that in 1880 there were on an average 560 bacteria in each cubic metre of air at Montsouris. In 1881 the average was 590, while in 1882 it was only 320. The highest numbers were recorded when the wind was north-east, and before reaching Montsouris had swept over a great part of the city. Ozone had no effect on the number of bacteria. The number is always small during rain, increases as the drying of the soil progresses, and decreases again if the dryness be prolonged beyond a week. In the centre of Paris, Rue de Rivoli, the number of microbes averaged, in 1882-83, 2490 per cubic metre of air, being nearly five times as many as at Montsouris. M. Miquel made experiments in the Alps on air from different altitudes, and he compares his results with the results obtained at the same dates in Paris, July, 1883. At an altitude of from 2000 to 4000 metres there were 0·00 microbes per cubic metre; on the Lake of Thun (560 metres), 0·80 per c.m.; near the Hôtel Bellevue, Thun, 2·50 per c.m.; in a room of the hotel, 60·00 per c.m.; in the park at Montsouris, 760·00 per c.m.; in the Rue de Rivoli, 5500·00 per c.m. The poorness in microbes shown by the mountain air is attributed by Miquel (1) to the lessening of pressure, and the consequent expansion and dilution, as it were, of the air; (2) to the lessened density, decreasing the power of the air to suspend solids; and (3) to the progressive disappearance of productive foci of bacteria. Miquel's researches, carried out at the Hôtel Dieu, and at Notre Dame de la Pitié, showed that in the wards the average for the year was 11,100 bacteria per cubic metre of air. "Taking the whole year through it was found that the increase and decrease of bacteria in the air of hospital wards obeyed laws very different from those observed in the open air. The hospital bacteria, in fact, reached their minimum at a time when the windows could be kept open in June, July, and August, when the average fell to 5500." The maximum of the hospital (28,000) was reached in January in very cold weather, when the number in the air of the street had fallen to 160. "If," says M. Miquel, "hospitals be built in the middle of cities the surrounding quarters must receive microbes, which are possibly not always harmless."

Assuming, as we may certainly assume, that microbes are the actual cause of some zymotic diseases, and that these microbes may be wafted to us through the air as readily as they may travel by other channels, we must still remember that happily something more than the microbe is necessary for the production of the disease, and this something is found in the conditions necessary for its growth. This implies not only moisture and a certain amount of

warmth, but also a soil suitable for the bacteria to grow in. That all plants do not flourish equally well in all soils is well known, and it is also well known that the presence or absence of some minimal ingredient in a soil may make an enormous difference in the resulting crop. This fact is very strikingly shown by Raulin's experiments on the growth of the Aspergillus niger, the mould which grows so luxuriantly on lemons and other acid fruits. M. Raulin grew this fungus in a fluid containing sugar, tartaric acid, &c., which he devised himself, and which he found gave uniform results. Raulin found that the total crop of fungus grown in this fluid in a dish of definite area weighed (when carefully dried) twenty-five grammes. Raulin's liquid contained $\frac{1}{30000}$ part of the metal zinc, and if this were withdrawn the resultant crop fell to 2·5 grammes, or only $\frac{1}{10}$ of what may be considered a full crop. Further, Raulin found that the addition of $\frac{1}{1500000}$ part of nitrate of silver stopped the growth altogether, and that the growth of the aspergillus will not even commence in a silver bowl, so sensitive is the fungus to the action of that metal.

These experiments are most instructive, as showing us what apparently insignificant trifles may cause the growth of an organism to flourish or languish. They make it less difficult for us to frame an hypothesis to explain why certain zymotics seldom occur, and never flourish twice in the same soil; why certain families are more smitten by certain zymotics, such as tubercle and scarlet fever, than others; why in times of epidemic some persons escape; why in the old days of inoculation for the small-pox the inoculated disease was seldom so virulent as the disease "caught" in the ordinary course.

A NEW HOSPITAL IN BRUSSELS.

A NEW hospital at Molenbeck, on the plateau of Koekelbergh, an outlying district of Brussels, has just been opened, and will form an important addition to the medical services of that town. The main entrance faces the rue Vandenbogaerde, and consists of a vast structure reserved as the dwelling of the director, M. Deneus, the pharmacy, the laboratory, &c. A wing of this building is devoted to the store rooms, the reception of out-door patients, bath rooms, and operating amphitheatre. By the side of the latter there is a small room where patients, who cannot support transportation to their ward after operations, may rest and gather strength. The patients, on admission, are compelled to take a bath at once and dress in the hospital uniform. There are eight pavilions for the patients and two of the pavilions have but one floor. They are situated longitudinally with the prevalent winds and are connected by an open passage or gallery. Altogether there are 155 beds; each ward contains sixteen beds, a nurse's room, bath, closets, and one isolation room. The accommodation is divided evenly for men and women. The two pavilions that have but one storey are reserved for infectious cases, and these are divided into twenty-two small rooms, each with only one bed. Large gardens surround the pavilions, and the wash-house, the dead-house, the post-mortem room, disinfecting stove, &c., are as far away as possible. The building is warmed by hot water pipes with two generators of 60 horse power, and it is said that a satisfactory system of ventilation has been established. The land cost £2200, the building £12,000, while a recent lottery produced £520 towards defraying the purchase of the necessary furniture. Considering that there are already several large hospitals in Brussels, and that, after all, the capital of Belgium does not possess 400,000 inhabitants, this new work of charity is highly creditable.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6209 births and 4127 deaths were registered during the week ending the 17th inst. The deaths showed a decline of 128 from the high number in the previous week, and were equal to an annual rate of 24·2 per 1000 of the estimated population of these towns in the middle of this year, against 25·0 and 24·9 in the preceding two weeks. During the last quarter the death-rate in these towns averaged 21·4 per 1000, against 23·0 and 21·2 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 16·0 in Hull, 19·1 in Brighton, and 19·2 in Derby. The rates in the other towns ranged upwards to 31·3 in Bolton, 31·6 in Wolverhampton, 31·6 in Plymouth, and 32·8 in Cardiff. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 375 and 372 in the previous two weeks, were 370 last week; of these, 108 resulted from whooping-cough, 70 from measles, 59 from scarlet fever, 50 from small-pox, 34 from diphtheria, 28 from "fever" (principally enteric), and 21 from diarrhœa. No death from any of these zymotic diseases was recorded last week in Brighton or in Plymouth, whereas they caused the highest death-rates in Sunderland, Preston, and Cardiff. The greatest mortality from whooping-cough was recorded in Bristol, Wolverhampton, and Preston; from measles in Preston, Sunderland, Leicester, and Cardiff; from scarlet fever in Leeds and Halifax; and from "fever" in Derby. The 34 deaths from diphtheria in the twenty-eight towns included 14 in London, 4 in Portsmouth, 2 in Manchester, and 2 in Salford. Small-pox caused 78 deaths in London and its outer ring of suburban districts, 2 in Liverpool, and 1 in Birmingham. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1079, 1013, and 1001 on the preceding three Saturdays, was 1009 at the end of last week; the admissions, which were 161, 171, and 224 in the previous three weeks, were 216 last week. The Highgate Small-pox Hospital contained 96 patients on Saturday last, against 87 at the end of the previous week; 29 cases were admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 370, 537, and 609 in the preceding three weeks, declined again to 552 last week, but were 53 below the corrected weekly average. The causes of 93, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Brighton, and Leicester, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Sheffield, Oldham, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 30·7 and 30·5 per 1000 in the preceding two weeks, further declined to 29·0 in the week ending the 17th instant, and was 4·8 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 18·3 and 21·2 in Perth and Greenock, to 33·4 in Paisley and 34·4 in Glasgow. The 709 deaths in the eight towns showed a decline of 35 from the number in the previous week, and included 30 which were referred to whooping-cough, 20 to measles, 13 to diarrhœa, 12 to "fever," 5 to scarlet fever, 3 to diphtheria, and not one to small-pox; in all, 83 deaths resulted from these principal zymotic diseases, against 110 and 94 in the preceding two weeks. These 83 deaths were equal to an annual rate of 3·4 per 1000, which exceeded by 1·2 the mean rate from the same diseases last week in the twenty-eight English towns. The 30 deaths from whooping-cough corresponded with the number in the previous week, and included 8 both in Dundee and Glasgow, 7 in Leith, and 5 in Edinburgh. The fatal cases of measles, which had been 38 and 26 in the previous two weeks, further declined to 20 last week, of which 14 occurred in Glasgow and 5 in Dundee. The 13 deaths attributed to diarrhœa corresponded with the number in the corresponding week of last year. The 12 deaths referred to "fever" exceeded the numbers returned in the preceding two weeks; they included 7 in Edinburgh and 2 in Glasgow. Three of the 5 deaths from scarlet fever, and all the 3 from diphtheria, were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 203 and 198 in the previous two weeks, were 199 last week, and exceeded by 94 the number returned in the corresponding week of last year. The causes of 105, or nearly 15 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 38·5 and 31·2 per 1000 in the preceding two weeks, was 31·0 in the week ending the 17th inst. During the thirteen

weeks ending the 27th ult. the death-rate in the city averaged 29·4 per 1000, the mean rate during the same period not exceeding 19·8 in London and 19·7 in Edinburgh. The 210 deaths in Dublin last week showed a further decline of 1 from the high numbers in recent weeks, and included 23 which were referred to the principal zymotic diseases, against 24 and 19 in the previous two weeks. Of these 23 deaths, 13 were due to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 3 to whooping-cough, 3 to measles, and not one either to small-pox, diphtheria, or diarrhœa. These deaths were equal to an annual rate of 3·4 per 1000; the rate from these diseases last week being equal to 2·1 in London and 2·5 in Edinburgh. The 13 fatal cases of scarlet fever showed a considerable increase upon recent weekly numbers; while those of "fever," whooping-cough, and measles scarcely differed from the numbers in the previous week. Ten inquest cases and 8 deaths from violence were registered within the city, and 64, or nearly a third of the deaths, were recorded in public institutions. The deaths of elderly persons showed a considerable decline from the number in the previous week. The causes of 27, or nearly 13 per cent., of the deaths in the city last week were not certified.

Correspondence.

"Audi alteram partem."

THE UXBRIDGE TRAGEDY.

To the Editor of THE LANCET.

SIR,—I enclose a full account of the facts bearing upon the medico-legal aspect of the above case.[1] In your editorial note on my last letter you say, "We can only express our regret that Mr. Bowlby should feel himself injured by what he conceives a misrepresentation of his evidence as to facts and opinion." I am obliged, Sir, for such an expression; but you can scarcely expect me to accept it as a sufficient apology for the annotation of which I complain. There can be no doubt this annotation implied that the prisoner was convicted through some gross inaccuracy in the medical evidence. It must be known to you that the public and the daily press have so interpreted it, and that it has been taken as the text for various articles whose chief aim has been to discredit scientific evidence in general. And although your paragraph was vague, and consequently I could not guess at its precise meaning, I would remind you that you made a definite charge against me, and that charge you have neither supported by one word of proof nor have you withdrawn it. I will ask you, then, to state definitely what were "the inferences of the medical witnesses" which "were at variances with similar known facts in other cases on record, *in which a shot has been fired by a suicide between the infliction of a mortal wound even of the heart—and death!*" for I feel I have a right to know in what particular point *material to the issue of the trial* such inferences were in your opinion erroneous. You disclaim my supposition that you hereby assumed it necessary to presuppose the possible self-infliction of other wounds after that of the heart, and say that you "obviously wrote with the purpose of illustrating what may be done after a fatal wound of a vital organ." If, Sir, you only wrote with that intention, will you kindly explain what bearing such illustration has upon the inferences of the medical witnesses? I stated in my last letter that I had allowed of the possible self-infliction of even a third wound in the deceased, in spite of the damage caused by the first two, and I said that your annotation implied the contrary. To this you have not replied. You write that "a wound in the back is peculiarly likely to be self-inflicted if the suicide falls forward or on his side while the arm, still clutching the pistol, is convulsively drawn, stiffened, and by the fall twisted back." That sentence undoubtedly implies that there was an easy and obvious way of accounting for the back wound in the deceased, and is therefore a serious imputation on the capacity and common sense of the medical witnesses. Against the acceptance of such an explanation I would urge first, that, instead of the diseased being found clutching the pistol, the weapon lay by his side; second, that instead of his arm being "convulsively drawn, stiffened, and by the fall twisted back," his right arm was beneath him as he lay on his face, and his left arm was outstretched above his head with the palm downwards on the ground. You will thus see that your suppositions are without a shadow of proof by way of support. It seems to me just about as "probable" that a man should shoot himself in the back after firing a bullet through his heart as that he should place himself in the position you so graphically describe, and until you adduce in evidence some of the numerous cases with which, from the way you write, you no doubt are acquainted, I feel sure you will allow me to differ from you as to the "likelihood" of the act in question.

And, then, I must again remind you of what I wrote in my previous letter. It is not sufficient to account for "a wound in the back." The question is, "Does your theory account for the particular wound found in the back of the deceased"? If not, then it is certainly misleading, for the natural implication is that it does account for it. Can you, and will you, explain how the deceased could himself, with the pistol in his own hand, inflict the wound I described to the jury, a full account of which is in the report which I enclose. You "believe" that one reason why "neither the counsel for the defence nor the jury were able to solve the difficulty" (referring, remember, to the infliction of the back-wound) "was that they were not clear as to the possibilities, probabilities, and certainties of the case in its medical aspect." Here again is another supposition unsupported by a word of proof, and therefore not demanding a reply. Will you then explain away the difficulty by accounting for the wound? You say that your information was derived from "the usually accredited channels," and as you do not deny my suggestion that it came from the daily press, I presume this is the source indicated. I have not altered my opinion that "it is scarcely fair to condemn the medical evidence upon such authority." On the contrary, in my own defence, and in the interests of medical witnesses at large, I beg to protest as strongly as possible against your action as Editor of an important medical paper in this respect. The case was one of importance, you might easily have obtained additional evidence, but instead of this you allowed yourself to be led away by insufficient evidence, and thereby encouraged a foolish outcry against not only myself, but medical witnesses in general. I do not in the least dispute that your "comments were made in the interests of justice;" I feel sure they were, but I believe you have been misled by inaccurate reports, and I feel confident that if you find such to be the case you will correct the error. It is in the same interests of justice that I ask you to publish both this letter and the full account of this case that I enclose; and, finally, I would remind you that I ask for an explanation of but two points—1. In what particular, essential to the result of the trial, were "the inferences of the medical witnesses at variance with similar known facts in other cases on record in which a shot has been fired between the infliction of a fatal wound, even of the heart, and death"? 2. Can you, and will you, explain either how and in what position, by your own theory or by any other, could the deceased himself, with the pistol in either hand, inflict the particular wound in his back which I have described in my report and in my evidence.

I am, Sir, yours truly,

Queen Anne-street, Jan. 6th, 1885. ANTHONY A. BOWLBY.

*** In THE LANCET of Dec. 27th, 1884, p. 1163, we stated "it did not at all follow because a bullet wound was found on the body of the deceased in such a situation that it could not have been self-inflicted, that therefore it proved a criminal act by another person. It might have resulted from accident during a struggle for possession of the revolver, or from justifiable homicide for self-preservation." And yet Mr. Bowlby could gather from another passage bearing on the same question nothing short of an attempt on our part to throw discredit on the medical evidence. Does it not occur to Mr. Bowlby that we have not shown ourselves altogether wanting in fairness, or even courtesy, by publishing his account of the case which occupied nearly *nine* columns of type? And does he fail to recognise the meaning of the following words included in the comment (p. 82) appended to his lengthy report?—"Concerning the bullet

[1] This statement appeared in our issue of the 10th inst.—ED. L.

wounds Mr. Bowlby says that Nos. 1, 2, and 3 were possibly suicidal, and No. 4 was possibly accidental, though it could not have been self-inflicted. We may at once say that we accept this interpretation as correct." Surely he cannot seriously contend that there is vagueness in the paragraph, intentional or otherwise; but be that as it may, we are content to leave the matter to the impartial consideration of our readers. Coming now to the second charge in Mr. Bowlby's indictment against us we are compelled to introduce Mr. Parrott's name, because in our previous notices of "the Uxbridge tragedy" we referred to the medical evidence in general, and not to any particular witness. Moreover, although Mr. Bowlby formally declined to implicate Mr. Parrott in any way, he wrote (p. 78, Jan. 10th, 1885), "Nevertheless, I may say that on almost all the main points we were entirely agreed"; and again at page 40, Jan. 3rd, 1885: "It is scarcely fair to condemn that evidence—given by Mr. Parrott and myself," &c. And, further, since Mr. Parrott has not disclaimed participation in the responsibility attaching to the communications of Mr. Bowlby, which cannot well have escaped his observation, we are the less reluctant to review and compare the testimony of both gentlemen, and in delivering our defence of the assertion at p. 1163, Dec. 27th, 1884, that "the inferences of the medical witnesses were at variance with similar known facts on record," &c. The quotations hereafter following are taken from a copy of the depositions before the magistrates. First, as regards the wound (No. 4 in the depositions, No. 3 in the report in THE LANCET) of the heart, Mr. Parrott stated in his examination-in-chief, "If a man had fired the shot that caused that wound he could not have fired another shot," and "supposing the other wounds to be suicidal, that must have been the last inflicted." In his cross-examination he substantially confirmed the above, for we find him saying, "The wound I saw in the heart of the deceased must have caused *instantaneous death;* by that I mean in a few seconds." Surely these inferences were, as we contended, at variance with similar known facts in other cases on record, in which a shot has been fired between the infliction of a fatal wound, even of the heart, and death. Mr. Bowlby was certainly more guarded than Mr. Parrott, but for all that his evidence, in our opinion, is open to criticism. During his examination-in-chief, it was elicited that "the effect of wound No. 4 (the one in the heart) would be to cause death within a minute or two at the latest, and in my opinion after that wound had been inflicted the deceased *could not* have caused any of the other wounds." Compare this with what Mr. Bowlby writes in THE LANCET, Jan. 10th, 1885, p. 80: "I felt, although highly improbable, it was yet *not impossible* for all three [the wound in the face, and the two in the chest—Ed. L.] to have been self-inflicted." Let it be noted that these statements had exclusive reference to the wounds *quoad* their dangerous nature, and so their bearing on the issue of incapacitation for further suicidal acts, and did not include the subsidiary question as to the distance from the body at which the shots were fired. To return to the depositions, we find Mr. Bowlby repeating or supporting his former evidence:—"I think, taking the three wounds in the front of the body, it would be almost impossible for a man to inflict the third [the one below the clavicle—Ed. L.] after having inflicted either of the other two." Nor was his resolution materially shaken by cross-examination, for he goes on to say:—"If the deceased had then [i.e., after the back wound had been caused by a supposed accident—Ed. L.] taken the pistol, he could not have inflicted the three front wounds; he could have inflicted the one through the cheek, and he could possibly have inflicted *another wound;* it is highly improbable that he could have inflicted the heart wound after he had inflicted the two such severe ones as the other two on the front of the body." If the above references do not represent the evidence of the medical witnesses at the trial—and we maintain that for all practical purposes the magisterial investigation is to be regarded as part of the trial—then we can only say we have been misinformed—misled, it may be. But whilst we admit that Messrs. Bowlby and Parrott acted with a full sense of their responsibility, and with the desire and intention of furthering the administration of justice, we hold that we only exercised a right and discharged a duty when we said, "The inferences of the medical witnesses were at variance with similar known facts in other cases on record, &c."—ED. L.

LUNACY LAW REFORM.

To the Editor of THE LANCET.

SIR, If the Government is really preparing a Lunacy Bill this is no doubt the time for those who have, or imagine they have, ideas on the subject to bring them forward. The public, the lawyers, and the medical profession are all more or less dissatisfied with the present laws, and with many of the prevailing lunacy arrangements; but their discontent is vague, and their ideas as to the proper remedies for the prevailing disorders are, like your own, unformulated and partly contradictory. You, as representing the medical profession, say you are going to reserve your ideas for the present. This, in my humble opinion, is an unwise course to adopt. You have denounced the present lunacy laws unsparingly, and you have not been over-tender in your dealings with the officials who administer them. Now, there are about 500 members of the profession in the three kingdoms engaged wholly, or in great part, in the treatment and inspection of the insane, and this considerable fraction of the medical world look to you for some guidance in regard to this matter. They are immensely interested in the lunacy laws, and they have had much direct experience of their working, but they know that that experience needs correction by comparison with that of the general profession. I may say at once that I believe they feel deeply the apparent want of sympathy with them exhibited by some portions of the medical press. I also believe that they will be greatly disappointed if the arrangements of the future for the treatment of mental disease do not tend to make them more an integral part of the profession than they are at present. They naturally feel that having taken to a very difficult department of the profession, in which their attention is much absorbed by matters that seem non-medical, where their positions are often isolated, and in which they are often largely under the control of practically non-medical Government and local boards, it is a little hard on them to lose the sympathy and support of their profession, when they are conscious that they have assiduously done the professional work assigned them by the law. They think that they know something of what would be for the benefit of the insane in future legislation, but for obvious reasons they do not like to take any initiative in suggesting new laws. I speak for my brethren in England rather than for myself; for here, in Scotland, the position of asylum medical officers is essentially a more medical one than in England: the traditions of their office being more medical; our visiting commissioners being medical men who do not sink their profession in their office; our asylums being almost all public, with medical men on our boards of direction; our practice not being confined to our institutions, but a good deal of it being outside them, where we meet family practitioners and see mental disease in its early stages and in its milder forms. The position of some of us as teachers in medical schools brings us into contact with the fresh inquiring minds of students, too. We are neither tempted here to become purely officials, nor, in order to hoodwink the public, to disguise our officialism under the misleading euphemism of "neurologist."

If I were to summarise my lunacy experience in England and in Scotland, correcting the results somewhat by my observation of the working of the laws regulating the treatment of the insane in Europe and America, I would say that

the following would be improvements in the present English Lunacy Laws:—

1. A provision for the treatment, with a view to recovery, of recent cases of mental disease without any certification or any word of legal "insanity" whatever.

2. Provisions for adopting different modes of interfering with personal liberty on account of mental disease, and placing it under suitable treatment according to the symptoms present in various cases, thereby harmonising the law with the medical facts.

3. A provision that reasonable appeals and complaints on the part of the insane, or those held to be insane, in regard to their liberty, shall be inquired into in a formal and judicial way, sometimes even publicly, under proper conditions, thereby taking the responsibility off relatives, doctors, and asylums.

4. A provision for the classification of patients in asylums according to their mental state, the structure and arrangement of wards intended for the different classes of cases being made conformable to the mental and bodily condition of the patients who are to inhabit them.

5. A provision for the removal from asylums and for suitable guardianship elsewhere of patients who have so changed in mental condition, without having recovered since their admission, that they no longer need asylum care.

6. A provision for the systematic training and education of attendants and nurses on the insane.

7. A provision for the hospital treatment in public institutions of all the middle-class insane who need such treatment.

8. A provision that would lead to the education of all medical students in mental diseases. This, I maintain, is an easy and practicable measure, in spite of assertions to the contrary; and I think our experience in the Edinburgh University has proved it to be so. Apart from the heavy responsibility thrown on medical men in having to treat mental diseases as family doctors, and the serious risk they run in their medico-legal acts *quoad* insanity, I am strongly of opinion that the mental symptoms in ordinary diseases do not always receive the attention they deserve through their not being looked for; or their importance not being recognised, that the initiatory symptoms of mental disease are often overlooked or misunderstood; that the facts of mental heredity as influencing diathesis, disease, crime, character, morals, and social life are not always taken into account as they should be by medical practitioners; and that the whole science of medical psychology is retarded, all this partly resulting from our students not having any education in the derangements of the mental functions of the brain. On the doctrine of chances, if this great subject was brought under the notice of all students more able men would be attracted to its further study and investigation than at present. It is difficult now to attract a sufficient number of such men, and as one cause of this I cannot acquit the discouraging tone of a portion of the medical press. If the mental functions of the brain are the crown of man's life, surely their derangements are worthy to be placed beside the derangements of uterine function in the curriculum of the medical student.

9. A provision that pecuniary advantage to anyone shall be absolutely dissociated from the deprivation of any insane persons liberty.

10. A provision that all visiting government officials for the insane shall be medical men of proved acquaintance with the subject.

11. A provision that for curative establishments a larger staff of medical men shall be employed than is common at present.

12. A provision that all public institutions for the insane shall be allowed to provide out of their funds such arrangements for scientific research as their responsible medical heads shall deem requisite.

13. A provision that all boards of direction of asylums shall include at least two or three medical men, either combined with the ordinary directors or forming a special [illegible] "medical board," with special powers of recommendation and veto.

14. A provision to protect the doctor who does valid and necessary medico-legal acts in regard to insane persons which the law authorises or directs him to do, just as a magistrate is protected in his official acts.

I could assign reasons for each of these suggestions, and refer to the States, where many of them are in successful operation, but this would unduly intrude on your space. These provisions, I think, would be good for the insane and good for the medical profession. There will be others which the public, the relatives of the insane, and the lawyers will insist on as being requisite from their point of view. A perfect Bill will be a happy combination of what is sound in the ideas of all, and will be founded on the experience of the working of past laws, on the most reliable scientific conclusions, on a generous public sentiment towards a helpless class, and on a due respect for personal liberty, with the real welfare of the insane as its keynote throughout.

I am, Sir, yours, &c.,

T. S. CLOUSTON.

The Royal Edinburgh Asylum, Morningside, Edinburgh.

*** Our correspondent has read our leaders on this subject, though all to little purpose if he has yet to learn that we have fully formulated opinions. As a matter of fact, when Dr. Clouston was pouring contempt, not too courteously, on our Commission on lunatic asylums in the *Journal of Mental Science*, we were formulating and propounding a scheme, from which he would seem to have borrowed a few ideas; to this scheme we strictly adhere.—ED. L.

To the Editor of THE LANCET.

SIR,—Among the various suggestions that have been made for the amendment of the lunacy laws there is one which I have not seen alluded to, and which in my opinion would do much to relieve the medical practitioner of his present responsibility in connexion with the duty of giving a certificate of insanity. Out of consideration for your space I will endeavour to give my suggestion as briefly as the subject, a legal one, will admit.

Among the matters provided for in the various Lunacy Acts it is ordered by Sect. 89 of 16 and 17 Vic., cap. 97, that on admission of an insane patient into any asylum or private house a copy of the order and certificates should be at once transmitted to the Commissioners in Lunacy. It is further provided by Sec. 87 of the same Act that if the order or certificates "is or are in any respect incorrect or defective," they may be amended within fourteen days, "provided, nevertheless, that no such amendment shall have any *force* or *effect* unless the same shall receive the sanction of one or more of the Commissioners in Lunacy."

On the approval or sanction of the Commissioners in Lunacy, therefore, the order and certificates *have force and effect*—that is, the amended document is endowed with certain distinct functions. What these are is explained in the next section, Section 88—namely, every person received into any asylum under an order complete in its different parts "may be detained therein until discharged as authorised by this Act," and in case of escape may be recaptured. Such are the powers alluded to as *the force and effect* of an altered or amended document, and surely they must equally belong to a document examined by the Commissioners and not requiring amendment. Again, by Section 99, 8 and 9 Vict., c. 100, it is enacted that every person authorised according to the Act to take charge of a lunatic, and who has received a proper order to do so, shall have power to detain, recapture in case of escape, and in any law proceeding which shall be brought against him for so doing, "the party complained of may plead" the authority of such order in defence, and this shall be a justification for "taking, confining, detaining, or retaking such lunatic or alleged lunatic." It is not distinctly stated, but in my idea it is implied, that the submission of the legal documents to the commissioners, for their official examination and direction for amendments, confers upon such documents an extra validity. It is ordered also by the statute that all orders and certificates relating to patients admitted since the last official visit of the commissioners or visitors shall, together with the licence in case of a private house, be laid before the commissioners, as well as all case books, admission books, &c., which shall be duly signed by them (8 and 9 Vict., cap. 100, sect. 65)—that is, everything relating to the patient, except the certificates themselves, are to be signed.

My proposition is, then, that at each visit of the commissioners or visiting magistrates, each new patient, or patients, received since the last official visit shall be specially examined, and the order and certificates relating to each case, and when found satisfactory shall be *counter-*

signed by them, and the authority of the original documents should then lapse and terminate, and the responsibility for the patient's detention rest upon the authority of the commissioners and visitors alone. This would give the assurance to the public that the patient was rightly detained, if anything will do so; and it would relieve the medical profession of a responsibility never ending according to the present working of the statutes. Everything as to the examination of the patients and signing of all the documents, *except the endorsement of the certificate*, is already provided by the Act, 8 and 9 Vict., cap. 10, sect. 62. The relief to the original certifiers by the corroboration of the legal authorities is all that is new.

I remain, Sir, yours, &c.,

Boreatton-park, Shrewsbury, Jan. 1885. W. H. O. SANKEY.

THE TREATMENT OF FOUL WOUNDS BY HOT AIR.

To the Editor of THE LANCET.

SIR,—The perusal of Mr. Leighton Kesteven's interesting paper on antiseptic steam irrigation of foul wounds induces me to offer you a description of a method of treatment by hot air that for some years I have used with marked success in cases of chronic, indolent, and varicose ulcers, syphilitic or otherwise, which are known to every practitioner, and are a source of annoyance to the patient and his friends from their offensive discharge. I employed a village carpenter to make the box I used. It is constructed of well-seasoned wood, the bottom, or floor, consisting of three layers about an inch apart from one another, the outer one of stout sheet zinc or tin plate, is that against which the flames of the spirit lamps impinge; the middle is of perforated zinc, and above that a wooden floor, also perforated by numerous holes. The apparatus is placed on the bed, and the limb put in it by lifting the two lids, which are perforated by holes for the escape of hot air and vapour; the spirit lamps, two or three in number, are lighted, and the temperature is quickly raised within the box to as great a height as can comfortably be borne by the patient, and maintained for two hours, the process being repeated morning and evening. Sprinkling the inside of the box with an ounce or so of terebene is of value in neutralising the offensive smell from a large ulcer, and also probably contributes to the stimulative effect of the hot air. In syphilitic cases calomel may be vaporised by sprinkling on the zinc floor above the lamps. Before placing the limb in the box I well wash off as much purulent matter as possible with a syringe and a solution of boracic acid. After removal from the box I apply a piece of lint cut to the shape of the wound, but a quarter of an inch smaller, and soaked in a saturated solution of boracic acid, and either no bandage or just enough to keep the lint in place. I need hardly add that the rapidity of healing will be greatly accelerated if the patient will maintain the horizontal position entirely during the treatment; in other words, keep his bed or sofa. I have found large chronic ulcers of many years' standing heal rapidly under this process, and the limb remain sound and useful for years with the help of an elastic stocking or bandage. I think both Mr. Kesteven's experience and my own go to prove that in heat we have a manageable as well as powerful stimulant which is undeservedly neglected in treating the class of cases referred to.—I am, Sir, yours truly,

January, 1885. DOUGLAS W. ESHELBY, M.D., &c.

DEATH DURING THE ADMINISTRATION OF ETHER.

To the Editor of THE LANCET.

SIR,—I am very sorry to add another to the list of deaths during the administration of ether. The facts respecting the case are as follows:—On Wednesday, the 14th inst., at 5 P.M., I administered ether to a man aged sixty-two in the receiving room of the London Hospital. It was for a dislocation of the shoulder a week old; he could bear no manipulation. I used Ormsby's inhaler and had the air-cap open to a small extent throughout the administration. The patient was fully under the influence of the anæsthetic in about the usual time, and the dislocation having been apparently reduced I stopped the administration. As the dresser was proceeding to put the strapping on I found that the reduction was not satisfactory. The man had just partially come round; so, without putting any more ether in, I put the bag again over his face. In about two minutes the reduction was completed (with the heel in the axilla), and I removed the inhaler about a minute afterwards. I observed that the man began to look pale and that his breathing had become very feeble. I ordered brandy, which was given hypodermically over the cardiac region; artificial respiration was at once commenced by one of my resident colleagues, assisted soon after by another, whilst I drew the tongue forwards. The battery was also procured and used. The dusky pallor increased in spite of our efforts, and though we continued artificial respiration for upwards of half an hour we failed to bring him round. It should be stated that at the time of removal of the inhaler on the second occasion I felt no anxiety; it was not till a minute afterwards that I observed the death-like lividity and pallor. On the first occasion there was struggling; on the second none. I had inquired as to his food previously, also as to whether he had any cough or lung trouble, as he was short of breath when I saw him, but he answered in the negative to the latter.

The autopsy was made by Dr. Turner, pathologist to the hospital, and the lungs were found emphysematous and congested. There was bronchitis with a quantity of mucus in the tubes; the lower lobes did not contain much air; at the upper part there was more œdema. Trachea congested, containing frothy secretion. Heart flaccid; right ventricle and auricle occupied by soft coagulum; great increase of fat on surface of same and very little muscular tissue; at apex it had nearly disappeared; slight thickening of valves; left side of heart normal. Pericardium universally adherent. Other organs fairly healthy. Dr. Turner considered that death had been brought about by fatty heart combined with bronchitis and emphysema. The man had about an inch and a half of fat on the abdomen. I heard afterwards that the patient had not been well at home, having fainted not long before coming to the hospital. I was assisted throughout the case by one of my colleagues.

I am, Sir, yours truly,

PROCTOR SELBY HUTCHINSON,

London Hospital, Jan. 19th, 1885. House-Surgeon.

REMARKABLE CASE OF SELF-INFLICTED WOUNDS CAUSING DEATH.

To the Editor of THE LANCET.

SIR,—With reference to your recent remarks on the conviction of Mrs. Gibbons and the medical evidence bearing on it, I beg leave to narrate the following case, which came under my observation.

In the summer of 1875 I was sent for hurriedly to see an officer. I found him lying on a couch with two incised deep wounds on the front of the abdomen, and one similar wound on the back, near the spine. Twenty-six incised wounds were found about the left breast, some of them penetrating the cavity of the thorax and others leading along the ribs; both hands were dreadfully mutilated; and lying close by the officer was a sword covered with blood and bent to an angle of about 45 degrees. He lived for several hours, and told me how he had transfixed himself by placing the hilt of the sword against the wall and then pressing forward on it; but, failing to effect his object, he made a second attempt. This time the blade, impinging on the spine, was bent, so that he had great difficulty in withdrawing it, his hands being cut severely in the effort. As death did not ensue, he then tried to penetrate the heart, but without success. A post-mortem examination verified his statement regarding the transfixion and the effects of the second effort at causing self-destruction.

Had this gentleman been found dead, I think it is extremely problematical whether any jury would have given a verdict of suicide, as such unusual power of self-mutilation is uncommon; and I am disposed to think that medical evidence would probably have tended to the idea that such wounds would not have been self-inflicted.

I am, Sir, your obedient servant,

WM. ALEXANDER, M.D.,

Aldershot, Jan. 1885. Surgeon-Major.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

To the Editor of THE LANCET.

SIR,—At the request of the Council of the Royal Medical and Chirurgical Society, Dr. G. F. B——— has kindly undertaken to edit a catalogue of the Society's large collection of engraved portraits of members of the medical profession. The value of the collection would be much enhanced if members of the profession would present any engraved or lithographed portraits (not photographs) of themselves or others which are not now in it. The resident librarian would have much pleasure in informing intending donors whether any portrait they may desire to present is already in the possession of the Society.—I am, Sir, yours, &c.,

53, Berners-street, Jan. 18th, 1885. BERKELEY HILL, Hon. Sec.

THE M.D. EXAMINATION AT THE LONDON UNIVERSITY.

To the Editor of THE LANCET.

SIR,—In the last number of your journal a gentleman who was rejected in logic and psychology, but who passed in medicine, at the recent examination for the degree of Doctor of Medicine at the London University, complains of having to repass in the subject of medicine should he determine to present himself once more for examination. Surely, Sir, this is an undignified complaint in one who aspires to a good degree. If the examiners found this gentleman well up last December, surely they should find him still better up next December. Are we to consider him "learned in medicine" whose knowledge vanishes within a twelvemonth? I myself was rejected in logic and psychology at the recent examination while passing in medicine, but I hold the degree I covet at too high an estimate to take the schoolboy view of your correspondent. I, for one, have no sympathy with those who would lower the standard of any medical examining body, and certainly not of a university which has done more, I believe, to further medical education than any other institution in the world. If anyone should doubt this remark, I have only to refer him to the Medical Directory, and let him travel through the list of names. In regard to a teaching University in London, I am not surprised at the cry for it, since many of the London hospital schools make no attempt at teaching, at all events at clinical teaching. In spite of the many remarks made to the contrary, I directly contradict the statement that our clinical teaching is unrivalled. I would ask any unbiased person to "walk the London hospitals" in the true sense of the word, and I contend that he will count the clinical teachers of medicine on the fingers of one hand. If then London would draw men away from Edinburgh they must look to their teaching staff. It is simply foolish for us to shut our eyes to the fact that we are in this respect behind Edinburgh. We have in a somewhat cowardly fashion, I think, been railing against the easiness of the Scotch (and among others the Edinburgh) University Examinations, without giving due prominence to the other side of the question. There is another point, I think, which has been overlooked, and it is that, apart from all other considerations, the men of the north of England go to Edinburgh, and other Scotch Universities, from simple nearness, just as the men of the south chiefly go to London. It is only in the nature of things that north Englishmen should tend to go to a near university, whether it be English or Scotch. Trusting, Sir, that my remarks will offend none,

I am, faithfully yours,

January, 1885. M. B.

PARIS.

(From our Paris Correspondent.)

A NEW SOCIETY.

A NEW Society is being formed through the initiative of some of the leading surgeons of Paris, and the committee of organisation is composed as follows:—Professor Trélat, President; Professor Verneuil; Dr. Hurteloup, hospital surgeon; Professor Chauvel, of Val-de-Grâce; Dr. Bouilly, agrégé, hospital surgeon; Dr. Charles Monod, agrégé, hospital surgeon; Dr. S. Pozzi, agrégé, hospital surgeon, secretary of the committee. The Society is to be named the "Congrès Français de Chirurgie" and the statutes begin with the statement that the object of the Society is to establish scientific relations between the national or foreign savants and practitioners who interest themselves in the progress of French surgery. A meeting is to be held annually in Paris during the Easter week, but the period may be altered according to the decision of the Congress. All qualified practitioners are eligible as members, and the subscription for each is twenty francs a year. Each member will be entitled to the volume of the "Comptes Rendus" of the Congress. A donation of 200 frs., paid before Feb. 15th, 1885, will give the member the right to the title of founder. If the amount be paid after that date the subscriber will become permanent member (membre perpétuel), and he will be exempt from further payment or annual subscription. The subjects proposed for the first meeting, which is to be held in Paris during the ensuing Easter week, are:—1. Etiology and pathogeny of surgical affections. It is desired that clinical facts and experiments which may contribute to the determining of the respective rôles of the figured ferments (microbes, &c.) and of the chemical poisons (ptomaines, &c.) in the pathogeny of septicæmia may be brought forward. 2. Indications that may be furnished to surgical practice by the examination of the urine. 3. The best dressings to be employed in military surgery in the field. 4. The treatment of cold abscesses: to distinguish between the treatment of ossifluent cold abscesses and that of cold non-ossifluent abscesses. 5. Operative indications in deep Wounds of the Abdomen. Besides these subjects, chosen by the Committee of Organisation, the following are recommended:—(1) The comparative value of an iliac anus and a lumbar anus in cancer of the rectum; (2) indications for gastrostomy; (3) origin and nature of coxalgia; (4) indications for trephining the skull in traumatic lesions; (5) the treatment of the pedicle in ovariotomy and hysterotomy; (6) the operations on tumours included in the broad ligaments. All subscriptions and communications are to be forwarded to Dr. Pozzi, 10, Place Vendôme, Paris, from whom any further information may be obtained.

SUPPOSED POISONING BY COLCHICIN.

Colchicin, the active principle of the seeds of the colchicum, recently discovered, is a most powerful poison, and has not till now, I believe, been adopted for criminal purposes, although the other preparations of the plant, when given in moderate doses, possess known therapeutic properties of great value. The extreme toxic nature of colchicin has been taken advantage of by a manufacturer of artificial flowers in Paris, who obtained the drug by surreptitious means under the pretence of requiring it for the purposes of his trade, ostensibly for dyeing flowers of a violet hue, but it is supposed that in reality it was for a criminal purpose, as circumstances have occurred which lead to the suspicion that he used it to poison his first wife, who died a short time ago, and who had been buried only a few weeks when he married his present wife, a girl of eighteen. From the smattering of chemistry that the florist had, he hit upon colchicin as being the most convenient for his purpose, as no trace of the presence of the alkaloid was found in the body after death. This circumstance, coupled with the symptoms with which his wife died, excited some suspicion at the time, which has been increased by the fact that the man had, shortly before her death, made two unsuccessful attempts to obtain the alkaloid at chemists' shops; and as the cause of death by the administration of this drug is as yet only an assumption, the body of the supposed victim is to be exhumed and submitted to an examination. I may here note that a chemist, writing on this subject, describes colchicin as a salt crystallised in the form of fine needles, without odour but of a bitter taste. It dissolves in water and in alcohol. One centigramme in solution killed a cat in a few hours. At the autopsies of the animals so treated the stomach and the digestive tube were always found to be excessively inflamed, just as if the parts were burnt. Meanwhile the accused man is under arrest, and the case is being thoroughly investigated.

THE FATE OF LOUISE MICHEL.

Louise Michel, the well-known socialist agitator, who is now in prison, is reported to be in a state of mind bordering

on insanity, which manifests itself by great nervous restlessness, hallucinations, starting in her sleep, and constant terror of being attacked by troops. In fact, her brain is evidently affected, and she is therefore to be transferred to a "maison de santé" to undergo appropriate treatment.

Paris, Jan. 20th.

VIENNA.

(From our own Correspondent.)

THE VIENNA MEDICAL SOCIETIES.

THE scientific activity of the diverse Medical Societies in Vienna, the first rank amongst which must be assigned to the I. a. R. Society of Physicians, has satisfactorily increased in the past year. The Society of Vienna Doctors (Wiener Medizinisches Doctorencollegium) have abandoned their original intention of competing with the I. a. R. Society, and now restrict themselves to reports on the progress in the different theoretical and practical branches of professional education in the place of the former lectures on original researches, a programme which proves acceptable. At the "Section Vienna" of the Union of the Lower Austrian Physicians, also, instructive meetings have of late been held. At one of these meetings Professor Stricker demonstrated his theory of inflammation and the circulation of the blood, by means of excellent microscopic views projected on to a wall of the room by the electric lamp. At the last meeting of this Society Professor Billroth discussed the antiseptics used in his clinics, and expressed the opinion that surgical success depended, not on antiseptics, but solely on the most scrupulous cleanliness.

THE EFFECT OF IODCOLLODIUM.

Strikingly different from the usually quiet sittings of the I. a. R. Society of Physicians was the last one of the past year. Seldom, perhaps never, has a sitting of this Society been the scene of such a passionate debate, and only the tact of the chairman, Professor Billroth, and the admirable moderation of Professor Albert, prevented the occurrence of a scandal. The order of the day was a lecture by Professor Weinlechner on the application of iodcollodium, in which he spoke of the prosecution of the late Dr. Spitzer, at whose trial he acted as expert, and by his evidence principally caused the condemnation of the defendant. Dr. Spitzer ordered a girl to apply iodcollodium (1 to 100) as a remedy for red hands. The girl's mother painted her little finger daily, but at the end of three weeks the finger became gangrenous, and had to be amputated. At the trial of Dr. Spitzer, he was, on the testimony of several physicians, sentenced to pay a large fine, and to forfeit the right of practising his profession. Dr. Spitzer appealed, and the Upper Court ordered that the opinion of the medical professors of the Vienna University should decide the case. Professor Albert, who had to report on it, exonerated the accused from blame, whereupon the Upper Court confirmed his decision and reversed the original verdict; but, meanwhile, Dr. Spitzer, in a fit of despair, had thrown himself into the Danube. In his lecture Professor Weinlechner tried to prove that the painting with iodcollodium of a finger, be it annular or in the form of a glove-stall, must necessarily cause gangrene, and that his evidence involved no injustice against Dr. Spitzer. He stated that he made his experiments with a child's supernumerary finger, which was curved like a hook. Professor Weinlechner alleged that this finger, which he painted twenty-three times with iodcollodium (1 to 100), had become gangrenous, but Professor Albert easily succeeded in removing the coating of iodcollodium which covered the top of the finger, and showed that the digit remained quite intact, being only made brown by the iodcollodium, and that no furrow of demarcation could be detected. Professor Weinlechner was forced to agree that in this instance gangrene had not occurred, but expressed the opinion that there was still a possibility of its occurrence later on. During the debate Professor Weinlechner repeatedly attacked the decision of Professor Albert, for which, pushed hard by his opponent, he afterwards apologised. Professor Albert stated that in the whole of medical literature no warning is to be found against the application of iodcollodium, and that in the case of Dr. Spitzer an injustice had been committed. At the first sitting in the new year Professor Weinlechner showed the preparation of the supernumerary finger, which had, meanwhile, been amputated. The finger, after having been repeatedly painted with iodcollodium, became swollen, bluish-red in colour, and its top gangrenous; the nail fell off and pustules covered it. The Society, however, seemed no longer inclined to debate afresh on this subject. This lamentable affair, which caused the suicide of a colleague, and reflected seriously on the reputation of another, admonishes us to be cautious in applying new medicaments.

COCAINE.

As to cocaine, something of interest can be communicated. Züntz, in Berlin, lays stress on the fact that cocaine is an effective poison, and that from two to four centigrammes of it kill rabbits, and five centigrammes prove mortal to dogs. The Vienna oculists and laryngologists, however, have had many successes in applying it. Professor Störk praises the anæsthetic effect of the cocaine on the pharynx and on the larynx, although he was twice unsuccessful with two individuals who were so excessively irritable that the application of cocaine did not facilitate the introduction of instruments into the larynx. Into the ear of a patient who was dull of hearing, and suffering especially from a humming in the left ear, he dropped a solution of cocaine (20 per cent.). The next day the patient related that several minutes after leaving the hospital he was overtaken by such a swimming in the head that he could not stand upright, and had to be supported to escape falling. Another application of a solution of cocainum muriaticum (2 per cent.) is worth mentioning, owing to its striking success and to the simple manner of the application. An individual who scalded himself with hot water, and had already blisters on the skin, suffered intolerably from the pain caused thereby. After fruitless attempts to afford him relief by the usual means the solution of cocaine was applied, and the pain immediately ceased. Cocaine applied to the eye causes widening of the rima palpebrarum. Dr. Koller attributes this effect to the insensibility of the cornea, whilst Dr. Königstein presumes an irritation of the sympathetic which enters the superior and inferior palpebral muscles. The Vienna dentists, too, apply the cocainum muriaticum. Even a solution of cocaine of 2 per cent. applied to sensible dentine renders it less sensible after one or two minutes. Cocaine mixed with glycerine to the consistence of a paste and then applied to a carious tooth renders it insensible, sometimes in the course of only ten minutes. This proceeding is especially to be recommended in the case of children.

THE BACILLUS OF MALLEUS HUMIDUS.

Schütz and Löffler have proved the existence of this bacillus, which is similar to that found in tubercle but differs from it in possessing a specific tincturing power. Several days afterwards Bouchard in Paris, too, described micro-organisms as the cause of malleus humidus. These micro-organisms were said to be roundish, somewhat elongated formations, cocci, which are constantly in lively movement in the liquor, and finally group themselves in the form of chaplets. These researches were made solely with animals affected with glanders. Several days since a female rag-picker was conveyed to the Vienna Hospital Rudolfsstiftung. On her face and body were pustules somewhat larger than variola pustules, besides nodules in the skin and in the subcutaneous tissue, from which matter oozed. Malleus humidus was diagnosed, and Dr. Weichselbaum found in the matter from the pustules, as well as in the discharge from the nose, in the blood, and in the urine of the patient, the same bacilli as Schütz and Löffler had described. Weichselbaüm tried, with complete success, pure cultures of this bacillus on flesh-peptongelatine, on flesh pepton, agar-agar, and on potatoes. The cultures grow slowly at ordinary temperatures, but very quickly at the temperature of the blood. On sterile potatoes the bacillus forms, first, light-brown, and then dark-brown, colonies. Even the formation of "Sporen" could be remarked; and, finally little wands ("Stäbchen") were seen, which dissolved and resembled cocci grouping together. All inoculations with the latter cultures into rabbits, sea-hogs, sheep, &c., produced malleus humidus. Consequently, Dr. Weichselbaüm is of opinion that these bacilli are those of malleus humidus. As to the micro-organisms of Bouchard, he points out that the French inquirer employed broth for his cultures and doubtless made his inoculations with polluted material. Professor Csokor, of the Vienna hospital for animals, lecturing on the 9th inst. on Glanders and on Tubercul

Consumption of Horses, referred to these researches. As to the bacillus, he said he was not in a position to agree entirely with Schütz's statements. He did not find any specific quality in Schütz's bacillus. That it forms "Sporen" is not surprising, as all bacilli which multiply according to the leptothrix form do so. If all error is to be excluded, the researches must be made when the object is still fresh or mixed with glycerine, or with magdala-red, nor must it have been heated or dried previously.

Vienna, Jan. 12th, 1885.

Obituary.

EVAN BUCHANAN BAXTER, M.D. LOND., F.R.C.P.

EVAN BUCHANAN BAXTER was born in 1844 at St. Petersburg, where his father, James Baxter, had resided for some years as a high official in the Education Department of the Russian Government Service. His father, a personal friend of Christopher North, was descended from an old Scotch Presbyterian family. In early manhood he had removed to Russia, and there married a Miss Ross, the daughter of a Scotch merchant who had settled in St. Petersburg, and of this marriage a daughter, who died in infancy, and Dr. E. B. Baxter were the only children. His mother died whilst he was still very young. His father also directed the English school at St. Petersburg during his residence there, and here Evan began his education. Soon afterwards, on being appointed Government Inspector of Schools in the province of Podolsk, Russian Poland, his father took up his residence at Kaminetz, where Evan was brought up and educated until the age of sixteen under the care of his parent and an old French tutor. To this early training, so different from that of an English public school-boy, many of the characteristic elements in his thoughts and actions must be ascribed. In October, 1861, he came to England, and entered the General Literature and Science Department of King's College. At that time he was a good English, German, French, and Russian scholar, and had read and appreciated most of the best literature in those languages, and had also a good knowledge of many of the Latin classics. He was then quite unacquainted with Greek. A friend writes, "He and the late Professor Clifford joined about the same time as myself, and both showed themselves distinctly superior to the rest of us." This was in one of the most flourishing periods in the history of the General Literature Department of King's College. In 1862, having made rapid progress in Greek history and literature, he obtained an open scholarship in classics at Lincoln College, Oxford, and stayed there for three terms. His college tutor was the present Professor Nettleship; and his intimacy with his tutor's brothers and family remained close and cordial until his death. His great ambition then was to become a classical scholar and Fellow, for which his linguistic accomplishments singularly well fitted him. His university career, however, was interrupted by the prolonged illness and the death of his father. He returned to Russia to nurse and attend him. On coming back he felt that he could not resume his place in College for his scholarship had lapsed in his absence—even if his views had not undergone very material changes in the interval.

Before leaving England, and whilst in Russia, he had studied deeply philosophical literature and the doctrines of the Positive school; and this, with other circumstances, determined him not to return to Oxford. "The only profession," he said, that attracted me was that of medicine, holding out as it did an opportunity for the study of physical science and a hope of comparative intellectual freedom." And so in October, 1864, he entered the Medical Department of King's College, and obtained the first Warneford Scholarship on his entrance. In 1865 he was elected a junior scholar with the late Professor A. H. Garrod and Professor Curnow, and in 1869 gained the first Warneford Prize. Whilst in the Medical Department, in 1865, he was awarded the Dasent Prize (open to the whole College, for an essay on some historical or literary subject which should be distinguished by accuracy of composition and purity of style, and usually won by students in general literature). The subject for the essay was "The Minor Poems of Milton." In 1868 he was appointed assistant house-physician to King's College Hospital, and 1868-69 he filled the office of house-physician. In 1870 and 1871 he became Sambrooke Medical Registrar to King's College Hospital; and the conscientious exactitude with which he performed his duties was blended with such unobtrusive kindness in unofficially teaching his juniors that he is most gratefully held in remembrance by them as an example of what a typical senior student may do in such a position. It was at this time that he began to be appreciated as not only a man of the first intellectual calibre, but also as a great teacher and an extraordinarily careful clinical observer.

In 1865 he matriculated in honours at the University of London; in 1866 and 1867 he passed the Preliminary Scientific and First M.B. Examinations; and in 1869 graduated M.B., obtaining the Scholarship and Gold Medal in Medicine and the Gold Medal in Midwifery. In the next year, at the examination for the M.D. degree, he was marked with a star as worthy of the Gold Medal for General Proficiency.

In 1871 Dr. Baxter was appointed Medical Tutor at King's College, and he held this post until 1874, when he was chosen as the successor to Professor Garrod in the chair of Materia Medica and Therapeutics, and as an assistant physician to King's College Hospital, and these offices he held until a month or two before his death. In 1872 he became a Member of the Royal College of Physicians, and in 1877 was elected a Fellow. (He had been elected an Honorary Fellow of King's College two years previously.) He was subsequently appointed an Examiner in Materia Medica and Therapeutics, and he also filled for five years the corresponding office in the University of London. Whilst still tutor to King's College he was elected on the medical staff of the Evelina Hospital for Sick Children on its foundation, and he worked diligently but unostentatiously at the diseases of children for the next nine or ten years, first in the out-patient rooms and then in the wards. In the intervals between his medical classes he translated Rindfleisch's "Pathological Histology" for the New Sydenham Society, edited the fourth edition of Garrod's "Essentials of Materia Medica," and made some valuable experiments with the "Cinchona Alkaloids on Bacteria and Colourless Blood-Corpuscles," which were published in the *Practitioner* in 1873. His accurate knowledge of technical pathology and his choice incisive English enabled him not only to give a faithful translation of Rindfleisch's work, but to present English readers with a more readable book than the original, and marked by an elegance of style such as is rarely met with in a translation of a German scientific work. In his edition of Garrod's "Materia Medica" he preserved every characteristic which has made this text-book so popular, and he added to it many notes on physiological therapeutics, so that for accuracy and conciseness it still stands pre-eminent. Subsequent researches have scarcely modified any of Dr. Baxter's careful statements. His experiments on bacteria and the colourless blood-corpuscles show his excellence as a microscopical observer, and were remarkable for their originality, precision, and completeness, and for the painstaking labour which they must have involved. In consequence of these researches he was asked by the Medical Officer of the Privy Council to carry out a series of inquiries, on the same lines as the preceding, into the value of disinfectants, and his results were embodied in the Report for 1875. In a review of his paper in this journal on April 1st, 1876, it is remarked, "Dr. Baxter has been enabled to arrive at definite quantitative results as to their efficacy against the different poisons, and thus to supply us with most important experimental data on which to found our disinfectant operations."

In the next year he wrote an article in the *British and Foreign Medico-Chirurgical Review* on the vaso-motor nervous system, which showed a complete mastery of the history and position of the subject at that time. In it he pointed out how far our hypotheses were from including all the facts in this branch of physiology, and how great must be our caution before we invoke its aid in explaining our daily clinical and pathological phenomena, and the modes of operation of our therapeutical agents. His large and accurate knowledge of skin diseases, derived from many years' work at the Blackfriars Hospital, at first under the instruction of Mr. Jonathan Hutchinson, is demonstrated in the paper on "General Exfoliative Dermatitis," which he contributed to the *British Medical Journal* in 1879. His lesser writings include a series of physiological notes with which he supplied the *Academy* for many years, and these are remarkable for their condensation and the clearness with which difficult and complex questions are placed before the general reader.

He also reviewed some biographical works for the same journal. In March, 1880, in conjunction with Dr. Willcocks, then medical registrar to King's College Hospital, he published a series of observations on the number of red corpuscles in the blood, and their chromometric value in health, acute febrile diseases, chronic diseases, and in those pathological conditions in which the blood is either the primary seat of the morbid process, or, at any rate, the theatre of its most conspicuous manifestations. Here, again, the charm of precision and of an exact quantitative procedure is well shown. A short note in *Brain* of January, 1884, welcoming the appearance of a Russian review devoted entirely to Neurology, was his latest literary work. In 1874 he married a lady who had been a nursing sister in the Franco-German war and in King's College Hospital, who survives to mourn her sad loss.

In 1881 Dr. Baxter was appointed Physician to the Royal Free Hospital, and the charge of instructing the lady pupils in clinical medicine was placed in his hands. He performed the duties most devotedly, fully believing that our profession should be open to both sexes, and the ladies could scarcely have had another physician as a teacher who would have so well combined courtesy and gentlemanly feeling with the knowledge of a thorough all-round clinical physician and the skill of a practised teacher.

Dr. Baxter attended most assiduously to his duties at the Council of the Pathological Society, at the Medical Board of King's College, and at Committees on Therapeutics at the Royal College of Physicians; but he was an infrequent visitor at the general meetings of our Medical Societies. The principal occasion on which he took an active part in the proceedings was in the debate on Rickets, at the Pathological Society in 1880. We may recall his appearance as a speaker unknown to a large number of his audience. A tall, delicate gentleman, of somewhat fragile physique, with a slight but perceptible stoop, well-proportioned and well-poised head, with dark hair turning grey, falling straight and smooth, and somewhat thinly scattered. His forehead was high and square, and clearly betokened a markedly intellectual and thoughtful mind; while the delivery of his well-balanced sentences accentuated the impression that a speaker above the ordinary was engaging the attention of his audience. His deep-set, penetrating, bluish-grey eyes, hidden by spectacles, his long aquiline nose, delicately shaped ears, small nervous lips, and finely cut chin, with a small moustache and whiskers, and an elongated squarely-cut beard tinged with grey, gave a characteristic Oriental rather than English cast to his appearance. His profile, especially when lit up by a smile, was strikingly handsome. He had fine hands, with long tapering fingers and filbert nails, and small feet. His presence was altogether most striking, and can hardly be fairly depicted to those to whom he was personally unknown. At that meeting he gave proofs, with his accustomed precision, that starch-feeding in 92 per cent. of the cases observed by him at the Evelina Hospital had preceded rickets, but he also pointed out the objections against the hypothesis that this was its only cause. The rigorous deductions that he drew from all his observations, and the cautions that he enforced against their absolute adoption, cannot be better shown than in this address.

We would supplement this description of how he appeared to his medical contemporaries by noticing some characteristics well known to all who were his personal friends. In investigating a clinical case, Dr. Baxter was most methodical: he first heard the personal history, inquired into the family history of the patient, and afterwards made a thorough physical examination. It was only then that he came to a conclusion as to the diagnosis, and he pursued the same method however trivial the case might seem to be. He was as minute and thorough in laying down the plan of treatment, and he insisted on every detail which he ordered being systematically followed. After he had examined a patient, he became dogmatic as to the nature of the disease, and the requisite regimen and diet which would cure it or alleviate its symptoms, and it was remarkable to see how implicitly his patients carried out his wishes and how thoroughly they believed in his prescience and judgment. The method which he adopted for ascertaining the nature of the affections for which his private patients consulted him was carried by him into hospital practice. Here, also, his examination was most thorough and his directions for treatment most precise, and it is especially in this particular that all who began to investigate and treat diseases under his supervision at King's College and the Royal Free Hospitals will have to recall his memory with lively feelings of gratitude. He exhaustively examined every case under his care. In addition to being a well-trained general physician, he was a well-versed specialist in cutaneous and nervous diseases, and could use the ophthalmoscope and laryngoscope with easy familiarity, whilst his knowledge of therapeutics and physiology was almost unique. As a lecturer, we need only say that students often attended his lectures on Materia Medica twice, and even thrice, so great was the attaction of his style, and so clear was his exposition of the many details embraced in his course of lectures.

His personal gifts were so numerous, his courtesy so like a remanet from a former generation, his humour so marked and yet so grave, that all who came within the boundaries of his charmed circle distinctly felt better men from being influenced thereby. A physician after the type of Graves and Trousseau; a *littérateur*, whose exquisite and well-balanced periods were chosen from an accurate knowledge of Dante, Goethe and Schiller, Turgénieff, Voltaire, Corneille and Racine, Chaucer, Spenser, Milton and Addison, besides the most important Latin and Greek classics and the best modern English writers; a scientist, with accurate information as to the history of modern medicine; and a man, modest and retiring, ever giving place to others, and whose acquaintance was the joy of a select number of friends,—such is a bald estimate of the man who has just passed away.

The history of his illness is briefly as follows:—He was always delicate, and early in his English life suffered from bronchitis; his digestive powers were feeble, and for many years he had suffered occasionally from attacks of intestinal colic, which increased in frequency before his fatal illness. In February, 1883, he felt weak and out of sorts, and unable to do his work as well as formerly, and towards the end of that month he was laid up with right pleurisy, with some effusion, from which he slowly recovered and was able, but with difficulty, to lecture in the summer session of 1883; in September the intestinal trouble became rather urgent and continued so throughout his life. In January, 1884, an attack of left pleurisy set in, but he again lectured throughout the summer session. In the autumn there were signs of breaking down at the apices of the lungs, and these were soon followed by albuminuria. Œdema of the legs was noticed in November, and late in December diarrhœa, almost uncontrollable, left him but little remaining strength. On the 12th inst. attacks of dyspnœa began, suggesting cardiac thrombosis, and these continued until his death, early on the 14th. He was quite conscious until a few minutes before his decease.

In conclusion, the first element of his character and the mainspring of his life and actions cannot be better expressed than in a quotation from the letter of an old friend. "I never knew him hint, or say, or suggest the slightest toleration of anything but what was honest, honourable, and just. He was without exception the *most accurate* man I ever met. I never knew him state anything as a fact which was not the fact and capable of verification. He was never inexact or exaggerated." His views on medical questions are clearly stated in an address to the King's College Medical Society in 1870 on Medicine and the Allied Sciences. "The advancement of medicine at the present day depends mainly on *scientific investigation*—on investigation conducted according to the received methods of biology; *the perfecting of the individual practitioner* in clinical study. With the latter, science has little or nothing to do; with the former, its connexion is most intimate." His elegance of style, precision in the choice of words, and wide culture may be gathered from the concluding sentences of that address: "To nearly all of us it is an educational instrument in the widest sense—our only chance of culture. To nearly all of us, medicine is not only an occupation, but a life. And in the recognition of this, that our occupation and our life are one, lies at once the acknowledgment of our shortcomings, and a ground of hope for further action. Stronger motives than those of mere ambition or curiosity stimulate us to exertions which, but for them, would seem too hard. The mastery over the past is of no avail, save as it gives us a key to the future. We should be like those early voyagers who, starting from their well-known home in some northern island, were drawn ever onward by the vision of some mythic El Dorado or Fountain of Perpetual Youth. This, indeed, they never reached; but

in their passage through warmer seas, into the atmosphere of the unknown, they were not left without reward, for every morning brought with it new horizons; every night, new stars." J. C.

H. T. LANCHESTER, M.D. LOND., F.R.C.S. ENG.

IT is with feelings of painful regret that we record the death on the 8th inst., from acute pneumonia, of Dr. Lanchester of Croydon, at the age of forty-six. Although comparatively young, he had attained a position that it is given to but few to reach even at the end of a long career, and his premature decease is justly regarded in Croydon and its neighbourhood as a public calamity.

Born in 1838 at Yoxford, in Suffolk, where his father, who survives him, was then in practice as a surgeon, he was educated at the North Walsham Grammar School, and afterwards apprenticed to a leading general practitioner at Banbury. In 1858 he entered as a student at St. Bartholomew's Hospital, and had for his senior teachers Sir George Burrows, Sir William Lawrence, Sir James Paget, Dr. Baly, and Dr. Kirkes. Regarded as one of the ablest men of his year, he was much noticed by the different members of the staff, especially by Burrows and Baly. In the wards of these physicians he worked assiduously, and in intimate association with, as fellow-students, several members of the present staff of the hospital, besides many others, amongst whom may be particularly mentioned Dr. Horace Jeaffreson of Wandsworth, and Mr. Edwin M. James of Melbourne. On leaving St. Bartholomew's he was appointed resident medical officer at the Victoria-park Hospital, where he remained for nearly three years. While he was working here with the late Dr. Peacock and with Sir Risdon Bennett his mind was strongly directed towards the study of diseases of the heart and lungs, in which in after years he gained so wide a reputation. Having taken the degree of Doctor of Medicine at the University of London and the Fellowship of the College of Surgeons, he went, on the special recommendation of Sir James Paget, to Croydon as assistant to Dr. Carpenter and Mr. Whitling. Though still very young and holding a subordinate position, he quickly made his mark, for he was able, shrewd, clear-headed, active, full of tact and sound judgment, and of indomitable perseverance. Socially, he became very popular, and widely known as a man of large views and general culture, while many were attracted by his knowledge of and taste for literature and art, by the charm of his manner, his absolute integrity of thought and act, his keen sense of humour, and his power of turning an argument by some story or anecdote well chosen and admirably told. It was soon found that his services were indispensable, and he joined Dr. Carpenter and Mr. Whitling as their junior partner. In 1872 he married the only daughter of Mr. Page of Lincoln: she is now left with five children to mourn their loss. As time went on Dr. Lanchester's position at Croydon grew year by year more prominent. He was elected surgeon to the Croydon Hospital, and became connected with many charitable and other institutions of that town, and surgeon to the Second Surrey Volunteer Corps. He took a leading part in the affairs of the south-eastern branch of the British Medical Association, and for several years acted as honorary secretary, the duties of which office he performed with such ability that on his retirement he was presented, at Reigate, with a very handsome testimonial. Many will remember the happily-turned speech which Sir George Burrows delivered on this occasion. In 1878 he was elected President of the branch, and amply justified the anticipations which had been formed on all sides of his fitness for the appointment. Dr. Lanchester was also a member of Council of the Medical Benevolent College at Epsom, and chairman of the new Alfred Wing Committee of the Croydon Hospital.

While never assuming or accepting the position of a public man, he yet found time to take part in a variety of good public works. A Liberal in politics, he became vice-president of the Croydon Liberal Association, and in 1874 he was elected to a seat on the School Board, of which, with a temporary break in 1877, he had ever since been a member. At the last election in 1883 he was returned at the head of the poll, and was soon afterwards made vice-chairman of the Board and chairman of the Finance Committee. In this latter office he rapidly gained a high reputation as a financial authority. His fatal illness appeared to take its origin in a chill caught at a meeting of the committee of the Whitgift Foundation, of which he was a governor.

It will be seen from this rapid and imperfect sketch how great an amount of work Dr. Lanchester contrived to accomplish. Never robust in health, it was a matter of surprise to all who knew him that, surrounded on every side by constant claims upon his time, he was able not only to discharge the duties of a busy practitioner, who always made his patients, whether rich or poor, his first care, and to keep himself well abreast with the progress of medicine, but also to perform punctually and without confusion or omission the duties of a variety of public appointments. Yet he did so; and that with a steadiness of purpose which made everyone respect and value his opinion, and with a spontaneous courtesy and light-hearted and humorous good-nature which won the regard and affection of all with whom he was brought in contact. Probably no man ever left behind him a more unanimous opinion of his worth. With intellectual endowments that placed him on an equality with the ablest minds in the wide circle in which he moved; with a kindness and warmth of heart the presence of which caused jealousy and rivalry to be disarmed and forgotten; with an unchallenged reputation for honourable feeling, rectitude, and candour; and with a plainly indicated aversion, not to say impatient contempt, for all that was unfair or disingenuous, it is no mere posthumous flattery to say that his was a rare and lofty character. It was not in his nature to do a questionable act or to follow a questionable course. His name is one that will long be held in honour.

During his last illness, which was of less than a week's duration, Dr. Lanchester was attended by Dr. Andrew of St. Bartholomew's Hospital, Mr. Whitling, Dr. Horace Jeaffreson, Dr. Duncan, Dr. Richardson, and Dr. Oscar Clark. It was unanimously agreed to accord him a public funeral, which took place on the 12th inst., and which was attended by the mayor (Mr. J. Cooper), the deputy-mayor, and other officials of the Corporation; by deputations from the Croydon General Hospital, the Literary Institution, and other public bodies; by a detachment of the Volunteer Corps, by a very large concourse of the principal inhabitants, by his late partner, Mr. Whitling, and by numerous professional and other friends, many of whom had come from a long distance in order to be present.

THE SERVICES.

WAR OFFICE.—Medical Staff: Brigade Surgeon William Cathcart Boyd is granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major Richard William Forsayeth is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major Robert Hyde is granted retired pay, with the honorary rank of Brigade Surgeon.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon Isaac H. Anderson, to the *Wild Swan;* Surgeon John Dowson, to the *Briton;* and Surgeon Evan St. M. Nepean, to the *Revenge.*

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following candidates passed the Primary Examination in Anatomy and Physiology for the diploma of Member at a meeting of the Board of Examiners on the 8th inst.:—

ANATOMY AND PHYSIOLOGY.—John F. Blurton, Frank Hues, and C. Herbert Harris, Birmingham; Edgar A. Field, Wm. E. Porter, and Walter W. Chamberlain, Edinburgh; Frederick W. Burnett, Louis Demetriadi, H. Newman Pullan, and Benjamin Wainman, Leeds; John Garth, Liverpool; John Blacklock, Joseph A. Jenkinson, and Richard Bilsborrow, Manchester; W. Drewett Arnison, Newcastle-upon-Tyne; Dominick A. D'Monte, Bombay and Edinburgh; Bertal H. Scott, Toronto; David Roxburgh, Glasgow; H. Leeds Harrison and Matthew H. Spencer, Cambridge; W. Gabriel Rockwood, Madras.

ANATOMY ONLY.—Norman Davis and Isaac G. Modlin, Newcastle-upon-Tyne; H. Harlow Sales, Leeds; H. Foreman Cartmel, Manchester.

PHYSIOLOGY ONLY.—T. Wilford Scott, Cambridge; James E. Brown Toronto; Jasper J. Garmany, New York.

(Candidates referred for three months, 5; six months, 3.)

Passed on the 9th inst.:—

ANATOMY AND PHYSIOLOGY. — H. Edward Gough, Paul de Cressé Potter, E. Meyer de Jong, and George W. Dowling, Manchester; Chas. J. Acton, G. Lewis Travis, and T. Makins Draper, Liverpool; A. Spiers Alexander and Leonard Williams, Glasgow; E. Brereton Hill, Cambridge and St. Thomas's Hospital; Preston King, Arthur H. Williams, and E. Mellor Light, Cambridge; G. R. Scott Banbury and Francis F. Jones, Bristol; A. Owen Davies, Edinburgh; Oliver Norris and F. P. Roesch James, Leeds; W. H. Helm, Leeds and Edinburgh.

ANATOMY ONLY.—A. Seymour Taylor, Newcastle-upon-Tyne; J. Ellison Finnie, Liverpool; S. H. H. Dowse, Dublin; P. Allison Linnell, Manchester; Herbert Clapham, Sheffield.

PHYSIOLOGY ONLY. — W. Mitchell Branson, Sheffield.

(Candidates referred for three months, 9; six months, 2.)

Passed on the 12th inst.:—

ANATOMY AND PHYSIOLOGY. — F. Mark Davies, Madras; F. Abraham Le Mesurier and J. Borrill Close, St. Bartholomew's; Upendra K. Dutt, St. Mary's; J. Kingham Reeves, Guy's; Charles E. Dawson and W. Brakenridge Pettitt, Leeds; Charles T. Samman and Morgan J. Rees, London Hospital; A. Knowles Ludlam, Manchester; A. Hugh Benson and S. Butler Day, Bristol; Ernest T. Habjam, Edgar H. Lingwood, and W. H. Compton, Charing-cross; J. Lea Henstock and J. Cobden Williams, Liverpool; Herbert W. Maclure, Cambridge; Frederick W. Hildyard, St. George's; W. C. Brown, Newcastle-upon-Tyne.

ANATOMY ONLY. — Charles H. Smale, Manchester; Albert Norman, Guy's; George Dunn, Bristol and St. Bartholomew's; Phillip J. Le Riche, University College; Wm. H. Hillyer, St. George's.

PHYSIOLOGY ONLY. —John H. Lister, Leeds; Edmund Cairtley, Cambridge.

(Candidates referred for three months, 5; six months, 3.)

Passed on the 13th inst.:—

ANATOMY AND PHYSIOLOGY. — W. Henry Blake, University College; W. Harmsworth Savory, H. Pywell Daniell, F. Augustus Watkins, and Brereton S. G. Nightingall, St. Bartholomew's; Henry Saunders, John Hewan, and W. Lloyd Mathias, St. Thomas's; Edwin H. Blake, J. Joseph Lewington, Geo. H. Francis, and Alban H. Moxon, London Hospital; W. Arnison Slater and A. Zell C. Cressy, Guy's; W. Grant Reily, Middlesex; Thos. A. Grieves, St. Mary's; Edward Cooper, Charing-cross; W. Arthur Griffiths, Westminster.

ANATOMY ONLY.—F. Jesser Wadham, St. George's; Sidney E. Rossiter, P. Vernon Dodd, Geo. R. Saunders, and Ernest Loveday, St. Bartholomew's; H. Ferrers Knyvett, Walter E. Kelbe, Courtney J. Fuller, and A. R. Field Evershed, Guy's; L. N. Hoysted, Charing-cross.

PHYSIOLOGY ONLY.—H. W. Rogers, London Hospital; Alfred Bowles, University College.

(Candidates referred for three months, 4; six months, 2.)

Passed on the 14th inst.:—

ANATOMY AND PHYSIOLOGY.—H. Augustus Edmonds, G. J. Padbury, and F. W. A. Bryden, Guy's; John Hill, W. Francis Read, J. Aloysius Feeny, C. Harvey Lewis, Sampson Low, J. E. A. G. Becker, and A. John Cromwell, St. Bartholomew's; Edwin Cooke, Reginald T. H. Bodilly, Evan J. Neville, and Absolom George, King's College; Ernest H. Crisp, St. Thomas's; A. Clifford Domford, London Hospital; G. H. Biden and E. Irving Day, Charing-cross; E. Llewellyn Williams, University College; William Challenor, Middlesex.

ANATOMY ONLY. — George C. Peachey, M. E. H. Wale, and G. W. B. Daniell, St. George's; Frank Gilpin and Arthur F. Tyrrell, Middlesex; James Bampfylde, Guy's; William Jones, University College.

PHYSIOLOGY ONLY. — Astley C. Roberts, Guy's; John Bate, London Hospital.

(Candidates referred for three months, 5; six months, 2.)

Passed on the 15th inst.: —

ANATOMY AND PHYSIOLOGY. — John Nixon and W. Gratwicke Heasman, St. Bartholomew's; Timothy J. Head, George W. Sequeira, Benjamin H. E. M'Crea, and A. G. Bateman Lory, London Hospital; Llewellyn Harris-Liston, P. Dansey Addis, and A. Pedro de Carvalho, University College; Robley H. J. Browne, Guy's; Benjamin Badcock, Charing-cross and Sheffield.

ANATOMY ONLY.—George Pender-Smith, Guy's; Frank Elias, University College; Lawrence Franklin, St. George's; T. Warne Sargent, London Hospital; Cecil R. Harper and J. D. Cree, Middlesex.

PHYSIOLOGY ONLY. — R. Wright and G. Gavin Morrice, St. Bartholomew's; J. Perceval Westrup, King's College; R. Conrad Fraser, Guy's; David C. Dunstan, London Hospital; Alfred Purvis, Charing-cross.

(Candidates referred for three months, 10; six months, 2.)

Passed on the 16th inst.:—

ANATOMY AND PHYSIOLOGY.—C. Ernest Thomas and Harry Baldwin, Middlesex; Henry J. Marston and Frederick H. Bence, London Hospital; G. Sidney Green, St. Bartholomew's; Arthur Shillitoe, C. Herbert Sharp, T. A. Burnard Cooke, and John W. Roberts, Guy's; Hubert C. Phillips, St. Mary's; Frederick W. Davidson, Frank W. Croft, and Edward O. Cox, Westminster; Ibar MacCarthy, St. George's; T. A. Barrett Plowman, C. Mortimer Lewis, and Philip H. Whiston, St. Thomas's; H. Havilland Roe and William Case, King's College; Henry F. Cleveland and George H. Jauffret, University College; Sampson G. V. Harris, Charing-cross.

ANATOMY ONLY.—G. Irvine MacMunn, Westminster; Edgar Gregson, St. Bartholomew's; George H. Metcalfe and George A. Slack, Guy's; Frederick C. Angear, Charing-cross.

PHYSIOLOGY ONLY.—Alfred R. Nicholls, Middlesex.

(Candidates referred for three months, 9; six months, 2.)

The following candidates passed the Second Examination under the Combined Examining Board for England on the 8th, 9th, and 15th inst.:—

George Belben Flux,
Herbert Shipton,
Charles Henry Pilliner,
} King's College.

(One candidate was referred for three months.)

The Library of the College will be closed on Monday, the 26th, and Tuesday, the 27th inst., at four o'clock, for the purposes of the Pass Examination for the diploma of Member.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 15th inst.:—

Crosbyy, Robert, Newcastle-on-Tyne College of Medicine.
Dimmock, Augustus Frederick, King's College.
Failes, Frederick George, St. Bartholomew's Hospital.
Glinn, Cornelius Frederic, St. George's Hospital.
Hutton, John Stuart, St. Thomas's Hospital.
Vernon, John James Dean, Guy's Hospital.

The following gentleman also on the same day passed the Primary Professional Examination:—

Alexander James Adie, Charing-cross Hospital.

The following candidates passed the Preliminary Examination in Arts on the 8th, 9th, and 10th inst.:—

SECOND DIVISION.

*Balding, Edmund.	Norton, Everitt Edward.
Bale, Rosa Elizabeth.	*Nourse, Stuart C.M.
Bowd, John William.	O'Sullivan, Carroll.
Dalby, Herbert Ernest.	Raynes, Sidney Herbert.
Daly, Charles William.	Roper, Arthur Leonard.
Green, Arthur Robert.	Smith, Alfred.
Hawke, Edward D. H.	*Smith, Stanley John.
Heywood, Tomás.	Spilsbury, Francis Hands.
Ireland-Smith, Normand.	*Walter, Richard A.
Jackson, John.	*Watson, Luther.
*James, John Morris.	Webb, Frank.
*Jobbins, Edwin.	*Williams, John Bayley.
Knight, Brodnax.	Wilmot, Hugh Begbie.
Litchfield, Ernest R.	*Witham, Ernest Wells.

* Passed also in Elementary Mechanics.

Passed in Elementary Mechanics alone:—

Newington, John. | Wood, Thomas Jason.

Passed in Greek alone:—

Wright, Richard Searle.

DR. J. RANDLE BUCK of Sidbury, Worcester, has been elected a member of the examining staff of the St. John Ambulance Association.

THOMAS HAYES, M.R.C.S., of Rathkeale House, has been placed on the Commission of the Peace for the County Limerick.

MR. J. C. CLARKE, M.P. for Abingdon, has offered to build, at his own expense, a cottage hospital for the borough, at a cost of about £1000.

Two of the daughters of the King and Queen of Sweden have, it is stated, been dangerously ill from the effects of poisonous wall-papers.

A MEETING of workmen's representatives for the purpose of extending the Hospital Saturday movement among the working classes was held in Liverpool on the 19th inst.

WE regret to hear that Mr. Robert De'Ath, coroner for the borough of Buckingham and Winslow district, has recently met with an accident by being thrown out of his gig.

A SCHEME for the establishment of a Foundling Hospital for Liverpool has received a considerable amount of support, and an appeal for subscriptions and donations has been issued.

MR. CHARLES W. GLASSINGTON, M.R.C.S. and L.D.S. Ed., has been elected President of the Students' Society of the National Dental Hospital, in place of Mr. H. G. Read, L.D.S. Eng., who has resigned.

THE plans for the new chemical laboratory at Cambridge have been approved by the syndicate. The building will accommodate 175 students working at one time, and the total cost of the building and fittings is estimated at £30,700.

PRESENTATION.—On Monday, Jan. 12th, at Newton Heath, the Committee of Dawson-street Dispensary, Manchester, presented Dr. C. McDonnell with a gold watch on the occasion of his transfer to Newton Heath, after being junior medical officer of the dispensary for two years.

SIR P. DUN'S HOSPITAL, DUBLIN.—An arrangement has been made by the provost and senior Fellows of Trinity College to pay an annual sum of £50 as a subscription to this hospital, on the condition that students of the College suffering from fever shall be admitted to the pay wards without charge.

A CONCERT was given in the Sheldonian Theatre at Oxford on Tuesday last, in aid of the funds required to complete the purchase of the Nurses' Home in Oxford, which has been established in memory of the wife of Sir Henry Acland, the Regius Professor of Medicine. Princess Christian took part in two pianoforte duets.

CANTOR LECTURES.—Dr. Poore's third and final lecture, to be given at the Society of Arts on Monday, the 26th inst., at 8 P.M., will be on "Soil as a Climatic Factor: the Peculiarities of Mountain Climates, the Application of Modern Views to some Old Facts, and the Practical Use to be made of them in lessening some of the Dangers of Tropical Climates."

THE Council of the Charity Organisation Society, at a recent meeting, considered the subject of supplying dinners to poor children in the public schools on a self-supporting basis. The opinion was expressed that free dinners should not be entirely discontinued, but the consideration of the subject was adjourned before a definite resolution was arrived at.

DUBLIN HOSPITAL SUNDAY FUND.—The total collections for 1884 produced a sum amounting to £4399 0*s.* 11*d.*, which includes not only the collections taken up in the various churches, but also special donations, and the proceeds of a football match, the latter contributing a sum of £54 14*s.* to the fund. As compared with the previous year an increase is shown of £186 4*s.* 5*d.*

FIRE AT AN AMERICAN ASYLUM.—On the 18th inst. the infirmary of the Illinois Hospital for the Insane at Khankakee caught fire, the flames originating in the furnace room. The weather was cold, the thermometer registering 12° below zero. The building was totally destroyed. Of the forty-five patients in the wards at the time seventeen were burnt to death, the remainder being with difficulty rescued.

ACADEMY OF MEDICINE IN IRELAND.—At a special general meeting of the Academy, held on the 17th inst., the following members were elected Honorary Fellows: Sir James Paget, Theodor Billroth, Prof. Virchow, Prof. Pasteur, Prof. Charcot, Dr. Austin Flint, Dr. Keith, Prof. Schroeder, Prof. Kölliker, and Sir Joseph Lister. At the same meeting the salary of the general secretary was fixed at £100 a year.

THE METROPOLITAN FREE HOSPITAL.—Building operations have been commenced upon the site which has been purchased by the committee of this institution in De Beauvoir Town, Kingsland, and which covers an area of 66,000 feet. The out-patients' department will, it is expected, be complete and ready for use by the end of March, while the whole building is to be finished by the end of the present year.

ANOTHER SCOTCH PROSECUTION UNDER THE DENTISTS ACT.—The same person who was convicted before the Sheriff of Edinburgh a short time ago, and fined £5 for falsely calling himself a dentist without being registered or qualified, has again been prosecuted and fined £20 for the same offence. It transpired during the trial that a separate fine may be claimed for each offence against the Act, and each repetition of an advertisement which is a false declaration is an offence.

MANCHESTER MEDICAL SOCIETY.—The following is the list of office bearers elected for 1885:—President: Mr. Walter Whitehead. Vice-Presidents: John Augustus Ball, M.B.; Charles Edward Glascott, M.D.; James Hardie, M.D.; Herbert Smith Renshaw, M.D. Treasurer: David Little, M.D. Secretary: Frederick Armitage Southam, M.B. Other Members of Committee: Charles James Cullingworth, M.D.; James Dreschfeld, M.D.; Abraham Matthewson Edge, M.D.; Richard Dacre Fox; Thomas Jones, M.B.; Siegmund Moritz, M.D.; James Ross, M.D.; Thomas Starkey Smith, M.B.; Arthur Edwin Sutcliffe; George Thomson, M.D.; Morrison Watson, M.D., F.R.S.; William Yeats, M.D.

BRITISH MEDICAL BENEVOLENT FUND.—The annual general meeting of subscribers to this Fund was held on Jan. 15th, at the house of the treasurer, Dr. Broadbent, when Dr. G. C. Jonson, chairman of committee, occupied the chair, in the unavoidable absence of the President, Sir George Burrows. From the annual report of the committee for the past year it appeared that the donations during 1884 have amounted to £722 18*s.* 6*d.*, subscriptions to £1307 3*s.* 9*d.*, a total of £2030 2*s.* 3*d.*, the increase in the amount of subscriptions being a noticeable and gratifying fact. The disbursements during the year had been—in grants, £1892 10*s.*; in annuities, £1107 10*s.*; in all, £3000; and the entire expense of collecting and distributing this large sum, over £5000, has been £152, about 3 per cent. The number of cases relieved during 1884 in the grant department was 168; and the committee felt that the amounts given by them to really needy and deserving applicants were, from want of funds, sadly less than the merits of the cases deserve. Seven fresh annuitants were elected; but there remain upon the list of eligible candidates no less than thirty-eight persons, all over sixty years of age, not one enjoying an income of £10, and mostly past work and practically penniless. Mr. Thomas Smith joined the committee; and Mr. France and Professor Macleod of Glasgow were elected vice-presidents.

WALLASEY MEDICAL CHARITIES.—On the 15th inst. a meeting of the subscribers and friends of the Wallasey Cottage Hospital, the Wallasey Dispensary, and the Seacombe Cottage Hospital was held to consider the best method of increasing hospital accommodation in the parish. Approval was, after a lengthy discussion, expressed of the scheme for building a new and larger cottage hospital at Wallasey, and also of the proposal to add to the cottage hospital at Seacombe, and to improve the arrangements at the dispensary.

EDINBURGH ROYAL INFIRMARY.—A meeting of the contributors to this institution was held on the 19th inst. for the purpose of receiving the report by a committee of the subscribers on the annual statement by the managers. The report, which was unanimously adopted, expressed satisfaction at the continued and increasing efficiency of the hospital during the past year, and urged the settlement of the question of providing special accommodation for fever patients by the Town Council, under the Public Health Act.

KING'S COLLEGE.—On the 21st inst. the twenty-fifth annual dinner of the past and present students of this institution was held in the College dining hall. In the unavoidable absence of the Lord Chancellor, Archdeacon Farrar presided, and among others present were General Sir Richard Wilbraham, K.C.B., General Sir J. A. Lefroy, K.C.M.G., Archdeacon Watkins, Dr. Priestley, Mr. T. M. Goodeve, Mr. Edward Clarke, Q.C., M.P., Professor Leone Levi, and a large number of associates and students of every department of the College.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At a meeting of this Society on the 8th instant, Dr. Hope, assistant medical officer of health for Liverpool, read a paper on Infantile Diarrhœa, in which he gave it as his opinion that the disease was due in the majority of cases rather to the absence of cleanly habits among the poor than to seasonal influences. He concluded by suggesting that a society which exists at Liverpool for the prevention of cruelty to children should supplement the labours of another institution in Liverpool which secures the attention of a midwife for poor women confined at their own homes, by introducing an efficient staff of trained nurses, whose duty it should be to visit periodically the young infants from the time the services of the midwife were discontinued. The paper was followed by a discussion, in which several members of the Association took part.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The following members were elected as officers and councillors for the year 1885 on the 12th inst.:—President: Mr. C. Spence Bate, F.R.S. (Plymouth). Vice-Presidents: Messrs. T. Charters White, George Gregson, Henry Sewill, J. T. Browne-Mason (Exeter), Richard White (Norwich), Andrew Wilson (Edinburgh). Treasurer: Mr. James Parkinson. Librarian: Mr. Felix Weiss. Curator: Mr. S. J. Hutchinson. Editor of the Transactions: Mr. J. Oakley Coles. Hon. Secretaries: Messrs. David Hepburn (Council), Robert Woodhouse (Society), Storer Bennett. Councillors: Messrs. F. Canton, Alex. Cartwright, Chas. S. Tomes, Wm. St. George Elliott, Augustus Winterbottom, Samuel Cartwright, A. Morton Smale, J. Howard Mummery, Arthur S. Underwood, J. F. Cole (Ipswich), G. C. McAdam (Hereford), W. E. Harding (Shrewsbury), Robert Reid (Edinburgh), J. R. Brownlie (Glasgow), J. H. Whatford (Eastbourne).

VICTORIA UNIVERSITY.—At a meeting of the Court of the University on Wednesday certain additions were made to the regulations affecting the time of admission of matriculated students to the Preliminary Examination in Science and to the First and Second M.B. respectively.

OXFORD UNIVERSITY.—The next examination for a vacant Radcliffe Travelling Fellowship will commence in the University Museum on Monday, February 9th, at 10 A.M. Candidates are requested to send in their names to the "Radcliffe Examiners, Radcliffe Library, Museum," on or before the last day of January.

THE CONTAGIOUS DISEASES ACT IN QUEENSLAND.—On November 21st the Queensland Legislative Assembly, after an animated debate, by the casting vote of the Speaker declared its disapproval of the compulsory examination of women under the Contagious Diseases Act. At a meeting of the Assembly, however, on Nov. 25th, a grant of money for the purpose of carrying the Act into effect was passed, the Colonial Secretary stating that he did not consider that the resolution which was carried on the casting vote of the Speaker should be regarded as an instruction to the Government to discontinue the operation of the Act.

PROPOSED NEW HOSPITAL AT HARROGATE. — The committee of the proposed new Bath Hospital have taken in hand a project for the erection of a new building, in place of the present dilapidated and badly constructed hospital, for the reception of 100 patients, estimated at a cost of £15,000, towards which amount certain sums have been already promised. The governors will be asked at the annual meeting to empower the committee to carry the project into effect, but no building will be commenced until about £10,000 has been promised. The sum is certainly a large one, but it is not too much for such a famous health resort as Harrogate, which has risen so immensely in public favour within the last few years.

MANCHESTER MEDICAL SOCIETY.—At the recently held annual meeting of this Society it was stated that the number of members now on the roll is 240, being ten more than last year. The library has been increased during the year by 302 volumes, and it now contains 28,118 volumes besides a number of unbound pamphlets. The statement of the treasurer (Dr. Little) showed that the income of the Society —including a balance at the commencement of the year of £144, members' subscriptions, £350, and a contribution from Owens College of £100—amounted to £629. The expenditure showed that £118 had been paid to the trustees, and that, after all necessary expenses had been defrayed, there remained a balance in hand of £139. After the adoption of the report, certain alterations of the rules were agreed to, and Mr. Walter Whitehead was chosen president for the ensuing year.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ANDERSON, JOSEPH, M.B., C.M.Aber., has been appointed Junior House-Surgeon to the Preston and County of Lancaster Royal Infirmary, Preston, vice F. D. Irvin, M.B.Lond., M.R.C.S., resigned.

CURTIS, ALBERT, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Staines Urban Sanitary District.

DIGHTON, A. ADAIR, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Resident Surgeon at the Branch Dispensary, Cheltenham.

FISHER, T. CARSON, A.B., M.D. Trin. Coll. Dub., has been appointed Consulting Physician to the Miller Memorial Hospital, Greenwich.

GENGE, RICHARD E., M.R.C.S., L.R.C.P., L.M., has been appointed Resident Obstetric Assistant to the Westminster Hospital.

HEATH, CHARLES J., M.R.C.S., L.S.A.Lond., has been appointed Senior House-Surgeon to the Preston and County of Lancaster Royal Infirmary, Preston, vice G. M. King, L.R.C.P.Ed., L.R.C.S.I., resigned.

JAGO, CHARLES SPRAGUE, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Somersham District of St. Ives Union, vice Grove.

LEIGH, WILLIAM WATKIN, L.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer and Public Vaccinator for the Gellyger Lower District of the Merthyr Tydfil Union, vice J. Leigh, deceased.

MCMURRAY, WAHAT, M.D., C.M.Q.U.I., has been appointed Medical Officer to the Walgett Hospital, New South Wales.

MATHESON, H. A. RIGBY, L.R.C.P.Ed., L.F.P.S.Glas., has been appointed House-Surgeon to the Launceston General Hospital, Tasmania, vice Thompson, resigned.

ORWIN, A. W., M.D., has been appointed Physician to the Guildhall School of Music.

POLLARD, FREDERICK, M.D.Lond., has been appointed Medical Officer and Public Vaccinator for the Chulmleigh District of the South Molton Union, vice T. Daly, resigned.

PRINGLE, J. J., M.B.Edin., M.R.C.P., has been appointed Assistant-Physician to the Middlesex Hospital.

SWAIN, JAMES, M.R.C.S., has been appointed Senior House-Physician to the Westminster Hospital.

WALFORD, WALTER G., M.R.C.S., L.R.C.P.Lond., M.D.Dur., has been appointed Surgeon to the St. John's-wood and Portland-town Provident Dispensary.

WEAVER, W. G., M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the Westminster Hospital.

WILDE, R. P., L.R.C.P.Ed., has been appointed Assistant House-Surgeon to the North Dispensary, Liverpool.

WILLS, W. A., M.R.C.S., has been appointed Junior House-Physician to the Westminster Hospital.

YOUNG, Mr. W. C., has been reappointed Public Analyst for the Whitechapel Board of Works District.

Births, Marriages, and Deaths.

BIRTHS.

CAMERON.—On the 18th inst., at "Lochiel," Harlesden, N.W., the wife of Charles H. H. Cameron, L.R.C.P.Lond., M.R.C.S.Eng., of a son.

COLMER.—On the 6th inst., at South-street House, Yeovil, the wife of P. S. H. Colmer, M.D., of a son (stillborn).

ROBERTSON.—On the 19th inst., at the Grand Avenue Mansions, West Brighton, the wife of Dr. Lockhart Robertson, F.R.C.P., of a son.

MARRIAGES.

CHAVASSE—HYLAND.—On the 22nd inst., at St. Saviour's Church, Camberwell, by the Rev. F. J. Chavasse, M.A., Rector of St. Peter-le-Bailey, Oxford, the Rev. L. T. Chavasse, M.A., Vicar of the Parish (brothers of the bridegroom), and the Rev. Percival E. Wilson, M.A., All Saints' Rectory, Birmingham, Thomas Frederick Chavasse, M.D., of Birmingham, and Barnet-green, Worcestershire, to Frances Hannah, only daughter of the late Arthur Hyland, Esq., J.P., of The Linthurst-hill, near Bromsgrove.

GILL—SARGENT.—On the 14th inst., at St. John's, Brixton, by the Rev. J. B. Patrick, Fitz-Henry Gill, of Tavistock, to Caroline Pearce, only daughter of D. W. Sargent, M.R.C.S., L.S.A.Lond., 364, Brixton-road. No cards.

IRVINE—HUGGINS.—On the 15th inst., at St. Thomas's Church, Portman square, by the Rev. F. Alexander Ormsby, M.A., Robert James Irvine, M.S., M.B., only son of Robert Irvine, Deputy Inspector-General R.N., to Helena Jane, widow of the late Wm. Farquhar Huggins, of Limpsfield.

ROSSER—CRICKMAY.—On the 15th inst., at St. Jude's Church, South Kensington, by the Rev. R. W. Forrest, D.D., Vicar, Walter Rosser, M.D., of Wellesley Villas, Croydon, to Edith Maud, youngest daughter of George R. Crickmay, F.R.I.B.A., 62, Nevern-square, South Kensington.

WILKINSON—BOND.—On the 13th Nov., at St. Mary's, Preston, Melbourne, William Cleland Wilkinson, B.A., M.B., B.Ch. T.C.D., eldest son of William Wilkinson, Beresford-road, Birkenhead, to Louisa Anne, only daughter of R. M. Bond, of Preston, Melbourne, formerly of Benambra, New South Wales.

DEATHS.

CAMERON.—On the 28th inst., at 316, Kennington-park-road, S.E., of phthisis, John Cameron, L.R.C.P., aged 32.

DAVIES.—On the 15th inst., at Plymouth, Elijah Knox Davies, M.R.C.S.E., late District Surgeon of Hanover, South Africa, aged 36.

HALL.—On the 14th inst., at Hampden-street, Nottingham, Charlotte, widow of the late Marshall Hall, M.D., F.R.S., aged 83.

MCCOSH.—On the 16th inst., at Bury-street, St. James's, John McCosh, M.D., late Bengal Army, aged 80.

MOORE.—On the 6th ult., at North-terrace, Adelaide, South Australia, Robert Waters Moore, M.R.C.S., F.R.S., President of the Medical Board of South Australia, and formerly Colonial Surgeon of the Province, aged 65.

NOBLE.—On the 12th inst., at his residence, Oxford-road, Manchester, Daniel Noble, M.D., aged 75.

PLAYNE.—On the 15th inst., at his residence, New Malden, Surrey, George Playne, M.D., aged 82.

PUCKLE.—On the 14th inst., George Puckle, M.D., formerly of Denmark-hill, eldest son of the late George Puckle, Esq., of De Crespigny Park, Surrey, aged 53.

RANDALL.—On the 15th inst., at Lansdowne-road, Croydon, Alfred Mayor Randall, M.R.C.S., L.S.A.Lond., in his 85th year.

TUCKER.—On the 13th inst., at Bournemouth, St. George Wade Tucker, M.D., of H.M.'s Indian Medical Service, aged 65.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, January 26.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Discussion (continued): Are Small-pox Hospitals necessarily (*per se*) a Source of Danger to the Surrounding Population?

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—8 P.M. Dr. G. V. Poore: The Chief Sources of Atmospheric Impurities, both Inorganic and Organic; Climatic Diseases and Climatic Health Resorts (Cantor Lecture).

MEDICAL SOCIETY OF LONDON.—Mr. Bowreman Jessett: Cancer of the Tongue; its Etiology, and an Inquiry into the Different Methods adopted for its Removal.—Mr. William Rose: A Case of Simple Depressed Fracture of the Skull; Trephining; Recovery.—Dr. Beevor will show a Case of Paralysis Agitans without Shaking.

Tuesday, January 27.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., and on Fridays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Moseley: Colonial Animals.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Mr. W. B. Dalby: Cases in which Perforation of the Mastoid Cells is necessary.—Mr. Barwell: Case of Simultaneous Distal Ligature of the Carotid and Subclavian Arteries for High Innominate Aneurysm.

Wednesday, January 28.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour. Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

HUNTERIAN SOCIETY.—7.15 P.M. Council.—8 P.M. Dr. Robert J. Lee: The Clinical Study of Infantile Syphilis.

Thursday, January 29.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The New Chemistry.

THE PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. James Cantlie: Degeneration amongst Londoners.

Friday, January 30.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—9 P.M. Prof. Pauer: Works of Living Composers for the Pianoforte.

Saturday, January 31.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Dr. Waldstein: Greek Sculpture.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

MEDICAL PRACTITIONERS AND REGISTRARS.

P. F. M.—The conduct of the Registrar, as reported in our correspondent's letter, displays an ignorance of his official instructions which is the more incomprehensible since he has held his appointment for twenty-five years. Each form for medical certificate of the cause of death bears on its face the words "Should the medical attendant not feel justified in taking upon himself the responsibility of certifying the fact of death, he may here insert the words 'as I am informed.'" It seems almost incredible that a registrar of twenty-five years' standing should be ignorant of this instruction, more especially as registrars are strictly enjoined to ascertain all the facts relating to a deceased person (including the date of death), except the cause of death, from the legal "informant," who is alone responsible for the accuracy of such information, and who signs the entry in the death register. We urge our correspondent, in the interest alike of the public, the profession, and the Registrar-General, to report the circumstances fully and precisely to that official, at the General Register Office, Somerset House.

PRURITUS VULVÆ.

M.D. asks for suggestions as to the best treatment of pruritus vulvæ, as he has a very obstinate case, which has hitherto resisted the usual local applications—nitrate of silver, soothing lotions, &c.

Vista.—No.

CAFFEINE.

To the Editor of THE LANCET.

SIR,—I shall be glad if you can find space for a few lines to draw attention to this valuable heart-tonic, which, though known and favourably spoken of by Continental physicians for twenty years, seems to have been comparatively little used in this country until very recently. My attention has been drawn to its use by the report of a clinical lecture by Dr. Dujardin-Beaumetz, Physician to the Hôpital Cochin, Paris, in which after summarising the various opinions which have been given as to its value and mode of action, he promises the students that they will have the opportunity of seeing "veritable resurrections effected in our service by this marvellous therapeutic agent," and recommends that large doses, even amounting to as much as two grammes (or half a drachm) a day, should be given in order to obtain the full benefit from its use.

Having at the time three cases under my care in which cardiac debility was a very marked symptom, in two of the cases as the result of a recent attack of rheumatic fever, in the third as the result of a long residence in India with continual ill-health while there, I determined to try caffeine, and have been much pleased with the result. In all three cases the improvement has been most marked, the heart's action being steadied and strengthened, and the vascular tension augmented. In one case a decided diuretic action was noted, and the only ill effect in any case was that on one occasion, a two-grain dose being taken as late as 8 P.M., the patient was kept awake till 3 A.M., apparently by the action of the medicine. I have not found it necessary to give larger doses than two grains three or four times a day, dissolved in water and flavoured with tincture of orange or gentian.—Your obedient servant,

Dulwich, Jan. 15th, 1885. H. NELSON HARDY.

J. H. Davies, M.B.—We apprehend that the certificate of such a midwife would be quite sufficient.

Mr. C. E. Steele (Liverpool).—The matter has, we think, been sufficiently discussed.

BRITISH MEDICAL BENEVOLENT FUND.

To the Editor of THE LANCET.

SIR,—I have great pleasure in informing you that a vote of thanks for the services you have rendered to the Fund was unanimously passed at the annual meeting of the subscribers, held yesterday.

I am, Sir, yours faithfully,

Clifton-gardens, W., Jan. 16th, 1885. EDWARD EAST, Hon. Sec.

PROMOTION IN THE INDIAN MEDICAL SERVICE.

Observer, writing from India on the above subject, says:—

"Great injustice has been done by the system of allowing the local governments of the different provinces to nominate their own surgeon-generals. These appointments are not mere local or provincial posts, but form part of the administrative appointments retained for the Indian Medical Service at the reorganisation in 1880. They carry with them the military rank, as well as pension, of deputy surgeon-general, and ought therefore to belong to the whole service, and not to any local section of it. But this is not the only power of interfering with promotion exercised by the local governments, for they are also allowed to select their own sanitary commissioners. Now, these, on attaining twenty-six years' service, are at once raised to the rank of deputy surgeon-general, and in this way the sanitary commissioners of the North-West Provinces, the Punjaub, and Bengal have lately, one after another, superseded all their seniors. There are only twelve appointments in the service which carry with them the military rank, pay, and pension of deputy surgeon-general, and half of these are practically in the gift of the local governments. Failure to obtain these appointments means to the men passed over not only a stigma on their reputation and a loss of rank and pay, but likewise earlier compulsory retirement, and a loss for the rest of their lives of the extra pension of £250 a year. Is it wonderful that under such circumstances deep discontentment should prevail in the service, especially among the senior men, when it is seen that however faithfully men may have served the Government for the best part of their lives, and however distinguished their war services may have been, their just claims to promotion may be put aside and over-ridden by the power thus placed in the hands of the local governments?"

Dr. Walter Sumpter.—Thanks; but the lines are unsuitable for our columns.

SPURIOUS VACCINATION.

To the Editor of THE LANCET.

SIR,—At a time when small-pox prevails to a considerable extent, it may not be inopportune to consider one possible cause, among the many, why vaccination does not afford us even greater protection than is actually the case. It seems agreed by those who have had the greatest practical experience of the subject, that spurious vaccination gives little or no protection against subsequent attacks of small-pox. Now, in any given case where vaccination has been performed, either the vaccination may not "take" at all, or active local results may be obtained, and these again may be either normal or spurious. In ordinary cases, so long as sufficiently active local manifestations have been secured, the operator is satisfied the vaccination has "taken," and there is an end of the matter. The utmost attainable protection against small-pox is supposed to have been obtained. But, in fact, whether this is so or not depends entirely on the character of the local phenomena. Normal vaccine vesicles running the normal course indicate the utmost possible protection; but if the phenomena are those of spurious vaccination, probably no protection has been obtained at all.

The appearances by which we may recognise spurious vaccination are: 1. Papules or vesicles appear, but die away without undergoing the normal development, leaving by the eighth day a scale, or perhaps a scab. 2. Vesicles may appear, irregular in form, being pointed instead of flat and depressed, and irregular in contents, these being opaque and yellow, instead of clear and colourless. They are attended early by an areola, which is irregular in distribution and disappears before the eighth day. 3. Vesicles arise, at first to all appearance normal, but burst before the eighth day, leaving a scab or a suppurating sore. Now, in several of these cases scars will obviously result; so that at a period remote from that of the vaccination mere inspection will not be sufficient to enable us to conclude that the patient has been efficiently vaccinated. The scars observed in any particular case may have been the result of a spurious, non-protective vaccination. Therefore it is of the greatest importance to observe at the time when the local phenomena are in progress whether we have to do with a normal or a spurious vaccination, since it is then, and only then, that we can form any satisfactory opinion as to whether real protection has been secured or not; and in every case of spurious vaccination the operation should be repeated with a fresh supply of lymph at the earliest opportunity till normal phenomena are obtained.—I am, Sir, yours obediently,

Gower-street, W., January, 1885. A. H. N. LEWERS, M.B.Lond.

*** Mr. Lewers' letter contains much that is deserving attention, inasmuch as it states with truth that all vaccination is not equally protective, and that the course of development of the vaccine vesicle is an important element in relation to the amount and duration of protection. We cannot altogether agree with Mr. Lewers that the cicatrix affords no evidence of the amount of protection. The evidence obtained from small-pox hospitals proves that where the cicatrices are foveated a subsequent attack of small-pox is likely to be less severe than when foveation is not present; and this is easily understood when we consider the changes which take place in the skin during the development of the normal vesicle on the one hand, and the advanced vesicle on the other.—ED. L.

Dr. Albury.—The medical officers of the army are permitted to attend private patients so long as this does not interfere with the efficient discharge of their duties.

NEWSPAPER MEDICAL DISCUSSIONS IN BIRMINGHAM.

WE regret to see delicate questions of medical science made the subject of letters in the newspapers of Birmingham. Henceforth, when any medical man begins a controversy on strictly medical subjects in a newspaper, he should remain unnoticed and unanswered by any other medical man. The subject of unseemly discussion in Birmingham was the use of Chian turpentine in cancer. This is eminently the kind of question which has no business to be discussed in a newspaper

Messrs. Essinger and Neuburger.—We are glad that our correspondents are so well pleased with the present demand for "Wood Wool;" but we fail to see that they have advanced anything to lead us to modify our opinion.

BARBED WIRE FENCES.

To the Editor of THE LANCET.

SIR,—I am sorry to see that an attempt is being made to introduce the use of barbed wire as a fencing into England, and sincerely hope that the press generally will follow your lead in protesting most strongly against the use of such a diabolical invention. I have sufficient confidence in the humanity of my countrymen to feel convinced that anyone who had seen as much of "the working of it" as I have, during my residence in Kansas, where it is very largely used, would upon no account allow a yard of it to be erected upon their property.

Within the past few months I have heard of numerous instances in which horses have been more or less injured by coming in contact with what you most aptly call "such a *chevaux de frise*." Three of these so-called accidents having occurred within a mile of my house, I am enabled to give the results. In the first case the horse was so badly injured that after lingering for a few weeks, doubtless in great agony, it had to be shot, because, as the owner informed me, "it got down, and we couldn't get it up again." In another case the victim was so severely gashed that when I last saw it, some six weeks subsequent to the accident, it presented a shocking appearance, and the chances seemed strongly in favour of a friendly bullet being ultimately necessary. In the third instance two men who had been engaged in tinning a neighbour's roof drove into a fence on their way home in the dark. Having a powerful pair of cutting pliers with them, they were fortunately enabled to sever the wire and set the horse free, but not until he had been considerably cut about, and had kicked the harness off, and the buggy to pieces.

The popularity of barbed wire appears to be already on the wane in this country; it most certainly is in this section, and in one State, Vermont, a law has lately been passed prohibiting the use of it.

My anxiety lest when I return to the "Old Country" I should find it defaced by such a brutal, unsportsmanlike, and therefore, I think I may safely say, un-English system of fencing must be my apology for troubling you with this letter.—I am, Sir, yours truly,

W. V. VERNON CHAPMAN.

Fairlight, Walton, Harvey County, Kansas, U.S.A., Dec. 23rd, 1884.

H. T.—This new chinolin compound has been described by Knorr of Erlangen in the article by Filehne in the Zeitsch. für Klin. Med., Band. vii., Heft. 6, 1884; Berlin. Klin. Woch., No. 20, 1884; Deutsch. Med. Woch., No. 24, 1884.

AMENORRHŒA TREATED BY PERMANGANATE OF POTASH.

To the Editor of THE LANCET.

SIR,—The following case, which recently occurred in my practice, may prove of some interest to the readers of THE LANCET, as it goes towards confirming the high opinion that Dr. Thomas Sanctuary holds of the permanganate treatment in the above disease.

I was consulted about Miss W——, aged sixteen years, in November, 1884. The history was that she menstruated for the first time in June, 1884, and again in September. At the time I saw her in November she was both nervous and rather anæmic, suffering from frontal headache and a dull pain in the lumbar region. I ordered her sulphate of iron and aloes and other tonic treatment, and an anodyne liniment, which she continued using for more than a month. Under this treatment her general health improved very much, but there was not the least sign of a return of the catamenia. Her mother being most anxious about the case, I thought it advisable to try Ringer's treatment. I procured some pearl-coated pills from Messrs. Richardson and Co., Leicester, England, a grain of permanganate of potash in each pill, made up with "kolin to prevent oxidation," one pill to be taken three times a day with meals. After nine pills had been used the catamenia returned; so that nine of these brought a result in three days that ordinary treatment failed to do in four weeks.—I am, Sir, yours faithfully,

CHARLES F. MURRAY, M.D.

Ashfield, Beau Parc, Co. Meath, Jan. 14th, 1885.

"FOUR TWIN BIRTHS IN SUCCESSION."

To the Editor of THE LANCET.

SIR,—From the register of baptisms in the parish of Lesmahagow, Lanarkshire, I am enabled to supply a second example of four twin births occurring in succession. This was in the family of James Hamilton, farmer, Southfield Farm, Lesmahagow, and Isabel Lawson, his spouse. The births, five of them twins out of a total of eight, were in order as follows:—1726, March 23rd, twins, boy and girl; 1728, Feb. 28th, girl; 1730, March 29th, boy; 1732, twins, boy and girl; 1734, Oct. 6th, twins, boy and girl; 1736, Sept. 5th, twin boys; 1739, Aug. 26th, twins, boy and girl; 1741, Oct. 31st, girl.—I am, Sir, yours truly,

Lesmahagow, N.B., Jan. 10th, 1885. J. B. DALZELL.

ANOTHER "CURIOUS MEDICAL ACTION."

OUR contemporary the *Islington Gazette* reports another case in which a patient sought to evade full payment of a medical bill by setting off the opinion of one medical man against that of another. The judge very properly declined to decide between two different medical versions of a sore throat, which, strumous in the first instance, as Mr. Berry said, might too easily, in the unhealthy state of some of the northern districts, become diphtheritic in the second, as Mr. Dunstan alleged. Judgment was given for the plaintiff, Mr. Berry.

H. D. F. will find in our current number an article setting forth our views on the subject.

"THE MEDICAL DIRECTORY FOR 1885 AND THE NORTH-WEST LONDON HOSPITAL."

To the Editor of THE LANCET.

SIR,—The letter of Mr. Craske, one of the secretaries of the North-West London Hospital, requires some little correction, which, with your permission, in my capacity as governor, I will now proceed to give.

In the first place, the statement that Sir A. Clark and Mr. Heath resigned "out of deference to the united request of the late staff" is an error. No united request was ever made to these gentlemen. This I have on the highest authority. It is true that they attended a meeting of the late staff, when the information by which (being busy men) they were rushed into rejoining was set right and discussed; and it was as the result of this meeting, "and owing to the questions discussed thereat," to use the language of Sir Andrew Clark, with which Mr. Craske must have been familiar, that these gentlemen, for the second time in the course of a few months, deemed it their duty to sever their connexion with the North-West London Hospital.

Secondly, the secretary informs the public that the resignation took place too late to admit of his communicating with the Medical Directory. Had he taken this course of his own initiation, instead of awaiting a process of extraction, his explanation would have been more satisfactory. The secretary says that I could have obtained information privately from himself, and would have best shown my goodwill towards the hospital had I done so. It is, however, because I feel strongly that hospitals should court, rather than fight shy of, publicity, even to the minutest details of their management, that I thought it my duty to communicate with your journal, as the recognised leader amongst medical publications. Mercy, for which the secretary asks, is no doubt a gentle virtue, and should be remembered especially in our private relations; yet we must not forget that in all questions between charitable institutions and the public who support them, the motto "Fiat justitia ruat cœlum" is a safer guide.

I am, Sir, your obedient servant,

A GOVERNOR OF THE NORTH-WEST LONDON HOSPITAL.

Jan. 19th, 1885.

ON THE RESULT OF EXTENSION AFTER TENOTOMY.

To the Editor of THE LANCET.

SIR,—May I ask those of your readers interested in orthopædic surgery whether it is an established fact, as generally stated, that after tenotomy the extension made use of in the after-treatment actually stretches the newly-formed tendon between the cut ends, say, like a piece of india-rubber?

I have recently operated on two cases of wryneck, one being a severe case with 2½ in. shortening on the affected side. My after-treatment in these cases was at first by elastic extension with a Martin's bandage; but finding this rather irksome, I commenced manual extension, with a very good result. One thing struck me, that on forcibly extending the divided tendon a distinct "give," accompanied by a "snap," was the result. I found that the upper end of the new tendon and the lower end of the old were separated abruptly for about an eighth of an inch; the nail and part of the tip of the index finger could be inserted into this sulcus; there was evidently no new material between the old and the new tendon. After a lapse of about twenty-four hours this sulcus was filled up with inflammatory lymph ("tendon callus," if we may so term it), which projected lump-like above the level of the old tendon; this after a time smoothed down to the normal tendon level.

Does not this show that whether mechanical and slow, or manual and quick, extension is used, the newly formed tendon is not stretched, but rather that the extension used opens up a fresh area of sheath, from which the new tendon is regenerated? If this separation is great, non-union is the result, the blood-supply being unequal to the demand of tendon-formative material.—I am, Sir, yours faithfully,

T. HENDERSON POUNDS, F.R.C.S. Eng.

Snodland, Rochester, Jan. 14th, 1885.

"THE PHYSIOLOGY OF THE FEET."

To the Editor of THE LANCET.

SIR,—I have already (THE LANCET, June to August, 1884) occupied in discussing this subject too much, I fear, of your space. But I would remark on Mr. Neve's letter that he admits the advantage in descending a hill of projecting the feet, so that the toes or front part first touch the ground. This in ascending a hill is obviously necessary. It would seem to be, at least, curious if it be best also when walking on a level surface to bring the heel first to the ground, as stated of the natives of Kashmir. Accepting the fact, we are still at liberty to prefer the Arab or the North American Indian as the model for that which should be.

I am, Sir, yours truly,

Gloucester, Jan. 17th, 1885. T. S. ELLIS.

"THE YEAR-BOOK OF TREATMENT."

WE are asked to state that the first edition of "The Year-book of Treatment," a critical review for practitioners of medicine and surgery, which was published last week by Messrs. Cassell, has already been exhausted, and a second edition is now in the press.

Dr. T. Dobson.—The most recent official report on the subject is the Report of a Committee appointed by the President of the Local Government Board to inquire into the several modes of treating Town Sewage, issued as a Bluebook in 1876; the committee consisted of Mr. Clare Sewell Read and Sir Robert Rawlinson, C.E., C.B. See also Mr. Henry Robinson's small work on "Sewage Disposal," published by Messrs. E. and F. N. Spon, 46, Charing-cross, 1880.

C. O. H.—We think that the coroner should have summoned the medical man who first saw the child. Our correspondent should complain to the coroner.

HEART INJURIES.

To the Editor of THE LANCET.

SIR,—The following case may be interesting to some of your readers, in connexion with recent discussions relative to gunshot injuries of the heart.

Last September I determined, opportunity permitting, to try to solve the question as to what caused the peculiar flight and death of birds known as "towerers," notably partridges. Amongst the cases examined one was of especial interest with reference to injuries of the heart. In this case the pericardium was lacerated, and on looking at the surface of the heart some portions of feather were seen entering its substance near its base; on opening the ventricle, in addition to some feather being seen, there was a No. 6 shot plainly visible on its inner surface. This bird, after receiving the injury, continued flying as if nothing had happened for about a hundred yards, when suddenly it flew upwards in an almost vertical direction to a considerable height, then fell like a stone to the ground, and when picked up was quite dead. Now, although the time that elapsed between the injury and death of the bird was of only very short duration, still, I think, most people will admit that the injury was a very severe one, and shows that in birds prolonged muscular exertion can take place even after severe injuries to such an important organ as the heart.—Yours faithfully,

Stanley Hospital, Jan. 16th, 1885. J. F. H. OWEN, M.R.C.S., &c.

Anxious Inquirer.—The question has been answered many times in our columns. See THE LANCET for July 14th, 1883.

Dr. R. Pringle.—Next week.

ERRATA.—In the report of the remarks of Dr. Wilson Fox at the meeting of the Clinical Society last week, page 108, line 34 of the first column, the words "the late" should have been omitted. The oversight arose in substituting in the proof the name of Dr. Burney Yeo for that of Dr. Mahomed.—In the letter of "C. L." on the "English Conjoint Board," published in our last issue, fourth and fifth lines, for "next year" read *this year*.

Clinical Lectures ON SCLERODERMA.

By H. RADCLIFFE CROCKER, M.D., M.R.C.P.,
PHYSICIAN TO THE SKIN DEPARTMENT OF UNIVERSITY COLLEGE HOSPITAL, PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

LECTURE I.

DIFFUSE SYMMETRICAL SCLERODERMA.

GENTLEMEN,—The first known case of this remarkable disease came under the care of Dr. Curcio[1] in 1752, and is quoted by Willan[2] as an example of ichthyosis cornea. Lorry also probably alludes to this disease in his "Tractatus de Morbis Cutaneis," in 1777; and isolated cases were recorded from time to time; but it was not until Thirial's paper appeared in 1845, describing two cases under the name of "sclérème des adultes," that the disease began to be generally recognised. It is of such rarity that only about a hundred and twenty cases of this form are on record; we are therefore exceptionally fortunate in being able to study it with four cases before us. The disease is of interest not simply on account of its rarity, but also from the insidious manner in which it attacks its victims, its strikingly peculiar features, and the permanent crippling that too often ensues. Among the many names that have been given to it, "sclerema" and "scleroderma adultorum" have shown their fitness, to some extent, by their survival, both expressing the same idea of "hardness" of the skin, which is the most conspicuous symptom; and the specific name of "adultorum" was given to distinguish it from a totally different affection, universally known as "sclerema neonatorum." But scleroderma is by no means unknown among children, and it would simplify matters to drop the specific title and use "scleroderma" only for the disease before us, as Kaposi suggests, and keep "sclerema" for the infantile affection. At the same time you must bear in mind that the disease often affects the deeper structures as well as the skin. Scleroderma varies a great deal in its extent and distribution, and three varieties or types may be distinguished which it is desirable for the sake of clearness of description to consider separately. These varieties are: (1) Diffuse symmetrical scleroderma; (2) circumscribed, usually unsymmetrical, scleroderma, or morphœa, as it is more frequently called; (3) diffuse unsymmetrical or mixed scleroderma. It is with the first variety that we have to do to-day; and it presents itself under two aspects—an infiltrated or, as it is less correctly called, a hypertrophic, and a shrunken or atrophic, form,—I will introduce the cases to your notice in the order of their severity.

The first case is that of a man aged forty-eight, and, as so often happens with rare and chronic cases, he has been in other hands before he came to me, Dr. Samuel West having shown him at the Clinical Society in January, 1883.[3] As we see him now, more than two years since the disease began and one year since he came under our notice, we find so much improvement that to the eye there seems nothing wrong. It is only on pinching up the skin in the nape of the neck and down the back and sides that we find it still stiff, difficult to raise up, and harder than normal; and where the finger is drawn along the skin with pressure there is still produced a broad white line with pink borders, to which the normal colour is only slowly restored. Even now he cannot raise his hands above his head without feeling that the skin of the legs is pulled upon; but this is nothing in comparison to what it used to be, and far different from the time when his mouth was pulled open when he put his head back. He states that since the commencement of his complaint his skin has felt worse on some days than others, and after drinking a glass of beer his skin always feels tighter, probably by causing some flatulent distension. The points I wish you to observe are the exactly symmetrical distribution of the disease affecting the upper limbs, the hands escaping, and the greater part of the trunk, with no sensible line of demarcation separating the diseased from the healthy skin; that at first the skin looked and felt distended, obliterating the natural wrinkles and lines, but rendering it rigid and hard as a frozen corpse; and the surface was paler than natural, especially if stretched, with some pink mottling. His previous history informs us that he is a publican, and, like most of his class, a sinner in regard to alcohol, and has had frequent attacks of gout; but with this exception his previous health has been good. He had not been exposed to cold, and there was nothing to suggest the nature of the exciting influence, though gout was probably a predisposing cause, and the onset and course of the disease were very slow and insidious, so that it took six or eight months to reach its acme. The decline of the affection has likewise been extremely gradual, but on the whole so continuous that we have every reason to anticipate a perfect recovery in due time. We will now pass on to Case 2.

Jane R——, aged sixty-seven, a laundress, came into the hospital as an out-patient during the vacation and was seen for me by Dr. Penrose. She was admitted on Oct. 23rd, 1884. She has never been laid up, even for a day; has had eight children, all but two of whom have died young, but there is no evidence of syphilis. Last Christmas she noticed that her shoulders were stiff in the joints, then the elbows, and afterwards the fingers were affected. About Easter the skin began to get stiff over the chest, then over the back of the neck, then the sides, and gradually the joints became less movable, and she had to leave her work on June 1st. Two months later the skin of the wrist became stiff, the stiffness spreading up to the elbows, then to the arms and over the deltoid to the shoulder, rendering all the joints in its course immovable. It next appeared on the left side of the face, and to a less degree upon the right side, so that she could scarcely open her mouth. The chin was also stiff, but not her lips, nor any part inside her mouth; the forehead was affected in a moderate degree. The skin of the insteps and toe-joints was stiff, but no other part of the feet and legs. She used to have pains in her joints both before and after the stiffness set in, and a great deal of itching of the affected parts at night, but no burning or tingling. In every other respect she feels quite well. On admission she was noted to be a healthy-looking, fairly well-nourished woman. The lungs, heart, and kidneys showed nothing abnormal, the bowels were regular, and the appetite good. But the disease, which had not reached its full development apparently when Dr. Penrose first saw her, is now rapidly clearing up; there is some difficulty in pinching up the skin of the epigastrium; there is slight hardness over the ribs on each side, more on the right than the left side; but the rest of the trunk below the third rib is quite free, although a short time back it extended below the level of the last rib. There was never any sharp line of demarcation where the disease ceased. Above the third rib to the clavicle the skin is of a creamy-white colour, very smooth and shining; the margin is not even, but fairly well-defined from the skin below it, which looks well, and the skin of the neck above is deeply pigmented of a dirty-brown colour. This smooth shining condition extends over the shoulder-joint, and below it for about two inches into the supra-clavicular fossa and outer side of the supra-spinous fossa, joining the deep-brown skin of the exposed part of the neck, and the forearms, as well as the neck, are much pigmented, mottled here and there with lighter shades. The skin is fairly movable in these parts but thicker when pinched up. All these changes are much more marked on the right side than on the left, where below the clavicle the skin is almost normal to the touch, except where there are some old cicatrices from burns; over the shoulder it is very smooth, white, and shining, and there is a pink mottling in the supra-clavicular region. This discoloured skin is not, however, in the parchment-like condition called morphœa, but is an error of pigmentation, with sclerosis of the deep parts. The skin of the arms is very firm to the touch, but not nearly so hard as it has been; less at the back than the front, and it is slightly whiter and smoother than the healthy skin; in some parts on extending the limb, the skin becomes paler and more resisting. The flexure of the elbow is free from the disease. On the forearms the flexor surface is less affected than the extensor in the upper part, but at the wrist the skin all round is very hard, and there is little flexion or rotation possible. The backs of the hands are the worst of any part now; the skin is as hard as wood, and scarcely movable, but

[1] Philosophical Transactions, vol. xlviii.
[2] Cutaneous Diseases, 1808, p. 208.
[3] His then condition is described in the Society's Transactions, vol. xv.; it is therefore not repeated here.

can just be pinched up; the surface is also mottled with dark-brown pigment as far as the knuckles, over which the skin is white; flexion of the fingers is prevented, but they do not look altered, though all except the little finger feel quite hard up to the end. The left limb has the same areas affected, but to a somewhat less degree. The dorsum of the feet and toes is quite hard up to the ankle in front, and on the inner side there is a band of hardness up the lower third of the leg. The skin over the dorsum is quite adherent to the subjacent tissues, and cannot be pinched up. The soles are free, but the right palm is rather harder than the left, which is scarcely at all affected. There are no patches or subcutaneous tubercles anywhere. Since admission the patient has been having Turkish baths three times a week, with general tonics and good feeding, which she much required, having been on very short commons for some weeks. Now there is still further improvement; the skin on the arms and upper part of the chest is much more supple, and more easily pinched up. In the last two baths the patient has perspired over the chest for the first time since she has been treated; the chest is better than the arms, which have not begun to perspire yet. There has been slight pain in the phalangeal joints for the last week. The legs are still hard, but pigmentation is diminished, and they sweat slightly; this is true also of the dorsum of the left foot, but not of the right. The hands are beginning to perspire in the bath.

These two cases are good examples of the so-called hypertrophic scleroderma, though, as I have said, it is really a condition of infiltration at first—hyperplasia of the connective tissue occurring subsequently, rather than hypertrophy; but the point I wish to impress upon you, and which the term hypertrophy was intended to convey, is that at this stage there is an increase of volume in the skin contents, so that the skin is over-distended and stretched, giving rise to the hardness and immobility to which I have already drawn attention, and sharply contrasting with the atrophic or diminished volume stage, of which I shall presently speak in describing the two other cases. Still, the infiltration in these cases is not simply serous, as there is no pitting even with the firmest pressure. You observe that in both patients there was marked symmetry in the distribution of the disease, though at the same time there was unequal intensity on the two sides; that the arms and upper portion of the body were the parts chiefly affected. This is the rule, for though the legs are not unfrequently involved as well, as in the second case, I do not remember any instance of this diffuse symmetrical form in which the lower half of the body was affected and the upper part free. In neither case was the line of termination of the disease a defined one, but it gradually shaded off into the healthy skin; this also is the rule unless the surface is affected, as in the case I shall show you presently. Notice also what comparatively little change there is in the skin covering to the eye alone, the slight alterations that have been described all pointing to a condition of ischæmia of the skin—incomplete in the male patient, in whom its presence was indicated by pink mottling and slow return of colour when the blood had been pressed out by the finger, a condition present in a less degree in the woman also. In a more advanced stage we see it manifested in other ways by a permanent collateral dilatation of the capillaries, in tufts or striæ, which is very marked in some instances, by the abnormal pallor or by pigmentation, which may be in spots, streaks, or diffused over a wide area, from pale-fawn to a deep-brown tint. This, too, will account for the diminution or absence of sweat and sebaceous secretion which is observable in these patients, and the diminished temperature of the surface at the commencement. These two patients, being on the road to recovery, do not exhibit the typical "frozen corpse" condition of the early stage, with the distended skin and stony hardness; the surface is cooler than usual, though it is never absolutely cold; still, from the condition before you to this is but a step which your imagination can easily take.

There are two other points to which I would call attention. First, the age of the female patient, sixty-seven. This is far beyond what is usual; most cases occur between twenty and fifty, and I do not remember reading of any case so old as this. The second point is the slow and insidious development of the disease, in the man so gradual and unaccompanied by other symptoms that he scarcely knew when it commenced; but this mode of onset is by no means always what occurs. In 1878 a girl, aged thirteen, was admitted into the East London Hospital under my colleague, Dr. Eustace Smith, who was kind enough afterwards to place her at my disposal. A fortnight before admission the patient, who was an inmate of an orphanage, complained of pain in her arms, for which a liniment was rubbed in, and it was then noticed that the skin was hard, and by the time she came into the hospital the whole surface of the body, except the eyelids, palms, and soles, was involved, together with the mucous membrane of the right cheek. Eczema all over the head had existed for three weeks, and was not altered by the supervention of the scleroderma. Her temperature was 101°, pulse 116, and a systolic murmur was audible at the apex. For three months her temperature ranged from as low as 97° up to 105° on several occasions, these high temperatures corresponding to attacks of pericarditis, of which she had several. Improvement in the induration, which was not preceded by œdema, set in within a week, and in three weeks some pitting could be produced in the face.[4] The induration steadily diminished, but it was nearly a year before it quite disappeared. This, then, is a great contrast in some respects to the other cases. The rapid onset, universal distribution, and speedy improvement are not common features; her age, too, is noteworthy, though there are now a considerable number of children's cases on record, the youngest being that of Dr. Norman Moore,[5] a boy aged two and a half, and one by Cruse[6] aged two. You noticed that the mucous membrane of the cheek was involved; this, too, has been observed in other cases, not only in the cheek, but in the tongue, soft palate, larynx, pharynx, œsophagus, and vagina. Finally, the presence of endocarditis and pericarditis without the articular manifestations of rheumatic fever, unless the pains in the arms at the commencement be taken in this sense, is very interesting, to which I shall recur further on. There is, however, a darker side to the picture I have endeavoured to draw of this disease, and we must now turn to it. These two women will furnish us with the materials for its delineation, and, taken with the others, they will make the description of the diffuse symmetrical form of this remarkable affection nearly complete.

CASE 3. Jane E——, aged thirty-nine, dressmaker, married, was much exposed to draughts in her occupation, and had very little exercise. Her father is alive, aged seventy; her mother died insane, at sixty years of age; and one of her brothers, five of whom grew up, died of rheumatic fever and heart disease, and one of diabetes; four brothers and her one sister are well. The patient had measles and erysipelas in infancy, a skin eruption in the flexures of the elbows when ten years old, and muscular rheumatism when twenty-one years old; there is no history of syphilis. Up to April, 1881, the patient was in excellent health, but during that month she began to suffer from pain in the elbows and hands. These pains continued, and in June of that year dropsy appeared in the feet and legs, and also to a less degree in the hands but not in the eyelids. The patient felt very weak and languid, and the urine was high-coloured, but not diminished in quantity. The dropsy lasted all the summer, and gradually merged into the present condition, which was fully developed by about the end of November; and from that time she states that there has been no material change in her condition, except that she has gradually lost flesh. Six months ago she had what she calls gout in her left foot. It came on suddenly in the night, and the inner side and dorsum were swollen and painful. It became worse for a day or two, and then gradually disappeared. The patient attended the London Hospital, under Dr Stephen Mackenzie, for twelve months, and was galvanised without benefit. Six months ago Dr. Corner, to whom I am indebted for the case, forcibly extended her fingers; this also proved useless. The patient is a short, rather thin, but healthy-looking woman; her lungs, heart, and urine are healthy, and the only defect lies in the skin and subjacent parts of the extremities. The small size of the forearms and hands will at once strike you; they might well belong to a child of twelve, the fingers are bent, the ring and little finger more than the others. The proximal phalanges of the first two are only a little flexed, but the second phalanges are bent at a right angle, and the terminal phalanges are slightly bent in the first and second fingers, much more so in the ring and little finger, and the proximal phalanges in these are also bent; the terminal phalanx of

[4] The case is published in detail in the Clinical Society's Transactions, vol. xii. [5] St. Bartholomew's Hospital Reports, 1873.
[6] Quoted by Kaposi, Hautkrankheiten, 1883, p. 558.

the thumb, on the contrary, is over-extended, so that the back of the thumb is concave. All the joints of the hand and wrist are nearly immovable. The skin of the forearm and the back of the hand is of a yellowish-white tint, mottled with a few dilated tufts and striæ of dilated vessels, the surface is perfectly smooth, dry, devoid of hairs, except over the first phalanges, cooler than natural, has a wooden hardness, and is closely adherent to the subjacent tissues, so that it is absolutely impossible to pick it up, and near the wrist it appears to adhere to the bones without any intervening tissue, and is everywhere tightly stretched over the contents; in short, the limb looks and almost feels as if it were an old ivory carving, while to the patient the limbs feel as if they were in a case. The palm, however, is scarcely affected, and feels rather moist, but the subcutaneous tissues are hard. The whole of the extensor surface of the forearms is implicated, except an area over the tip of the olecranon, about an inch and a half in diameter. On the flexor aspect the disease extends up to the junction of the upper fourth with the lower three-fourths, where it terminates abruptly to the eye, but under the finger it can be felt extending more than an inch further subcutaneously; an oval area of nearly four inches over the flexors has escaped the induration, and bulges above the depressed ivory-looking skin. This and the free area over the olecranon allow free flexion of the elbow-joints, and there is slight power of pronation, but she cannot extend her elbow beyond an angle of 60°. Above the elbow the induration extends over the lower third of the limb posteriorly, but the skin is healthy in front, over an area equal to about a third of the circumference of the limb, and the edges, especially on the inner side, have an irregular but well-defined outline, and the induration becomes more and more superficial; so that although it is of the same ivory hue, the skin can be readily pinched up, feeling rather like parchment, as it is not at all adherent; in short, the skin alone is here implicated, for about an inch beyond the healthy skin. The two limbs are exactly symmetrically affected, but the left side is slightly harder than the right. On the lower limbs, beginning at the root of the toes, the induration extends all over the dorsum of the foot and extensor aspect of the leg as far as the knee, where it misses the skin over the patella, and then implicates the lower two-thirds of the thigh, but more superficially on the flexor aspect, the hardness begins just above the heel and implicates the leg nearly as far as the knee, and the thigh in its lower two-thirds; but the flexure of the knee is quite free, and so are the toes and sole. The movement of the toes is only slightly impaired, but the ankle is almost fixed, the knee, however, is quite free in all its movements. The symmetry of distribution is as exact for the two lower limbs as it is for the two upper, and the whole condition is almost exactly the counterpart of that of the arms and hands. It is most marked round the ankles and lower parts of the legs, and is very slight and superficial in the thighs. The surface is pale mottled or fawn-coloured in some places and rose-coloured in others, from the presence of dilated capillaries. The skin is quite smooth now, like the arms, since she has had the Turkish baths and shampooing, but when I first saw her the arms were rather rough from dryness of the cuticle, and on the lower parts of the legs there was a condition approaching ichthyosis. The rest of the skin is quite free from induration, but in the nape of the neck three or four subcutaneous firm nodules ranging from the size of a pea to a small bean are to be felt, and she says that in the early period of the disease there were a great number of them. None of these nodules are to be felt elsewhere.

(To be concluded.)

THE CITY DISPENSARY.—The annual meeting of the supporters of this institution was held on the 21st inst., when the ninety-sixth annual report of the committee was read. The number of patients on the books at the beginning of last year was 1107, and during the year there had been admitted 15,157, making a total of 16,264 patients treated during the twelve months. The income amounted to £2129 and the expenditure to £1436, leaving a balance of £693 in the treasurer's hands, against £822 at the end of the preceding year. After the transaction of some routine business, it was unanimously resolved that an honorarium of fifty guineas be given to each of the medical officers connected with the institution, in consideration of their valuable services during the past year.

ON

SOME COMPLICATIONS OF TRACHEOTOMY, WITH ILLUSTRATIVE CASES.

BY ROBERT WILLIAM PARKER, M.R.C.S.,
SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN.

(Continued from p. 152.)

2. *Chronic Laryngeal Catarrh.*—In children, the chronic conditions which may demand tracheotomy are: (*a*) chronic laryngitis, and (*b*) warty laryngitis (papilloma). From a consideration of the pathological anatomy of these conditions it will at once be evident that obstruction to the breathing may sooner or later come on, and how and why a little fresh catarrh or the occurrence of an exanthem or of whooping-cough may suddenly render these conditions of very serious import, and introduce an element of danger which will be great in proportion to the youth of the patient.

(*a*) *Chronic laryngitis* is usually secondary to an acute attack; and when it attacks the larynx, in a majority of instances it is by direct extension from the pharynx, or it depends on some constitutional peculiarity. Chronic catarrh leads to enlargement of the racemose glands and to general thickening of the mucous membrane and submucous tissue; the calibre of the larynx and trachea is thus narrowed; moreover, there is increased secretion of mucus, which is very tenacious, hard, and difficult to cough up. Owing to their small size in early life, stridor and dyspnœa quickly supervene on the slightest exacerbation of the conditions—such as that produced by simple catarrh, for instance. In other cases the onset of dyspnœa is very gradual; it is at first most obvious during the night when the child is asleep, and little by little as it progresses sleep becomes much disturbed. The stridor then becomes audible during the day-time, and is worse after crying or emotion of any kind. On examining the chest, the soft parts will now be found to sink in with respiration, and in children old enough to talk an alteration in the tone of the voice will become noticeable. Gradually the breathing becomes more and more laboured, and the voice, which is hoarse from the first, is finally suppressed. The following is a typical case.

CASE 3. *Chronic Laryngitis; no obvious Cause; urgent Dyspnœa; Tracheotomy; Difficulty in removing Tube; Recovery.*—C. B——, a little boy, aged four years, was re-admitted into the hospital on account of an increasing dyspnœa. He had already been under observation a few weeks previously for the same condition, for which he had been successfully treated with iodide and bromide of potassium, and local astringents. The condition had come on so gradually that the exact date of its first onset could not be fixed. At first it was chiefly noticed at night; then became evident during the day; there had, however, been slight exacerbations from time to time whenever the boy cried or caught cold; his voice had been hoarse for some time past. At the time of his readmission his symptoms were almost urgent; his pharynx on examination was swollen and congested; the epiglottis also appeared thickened; the voice was hoarse and half suppressed, and he spoke with great effort. He was immediately placed in a croup bed, and sedatives were added to the warm moistened air he was made to breathe; after a while he improved slightly. His dyspnœa was always worse at night; for two or three nights after his admission, between 11 P.M. and 2 or 3 A.M., the breathing was so laboured that tracheotomy seemed unavoidable. However, towards morning, the violence of the attack passed off, and he slept in comparative ease. Matters continued like this for a week, and as there was no permanent improvement in his condition, tracheotomy was performed. Subsequently he did well; his anxious, careworn expression gradually wore off, he slept soundly, his appetite and spirits and strength returned. I need not detail all that transpired within the next three months, during which he had to wear his tube. We tried his breathing power on several occasions, but he could not get on for very long without his tube. The boy was of a highly nervous temperament, and he greatly dreaded its removal. A subterfuge was finally adopted; a window was cut in the tube just at the angle, and the external orifice was corked; this obliged the boy to breathe through the glottis, while

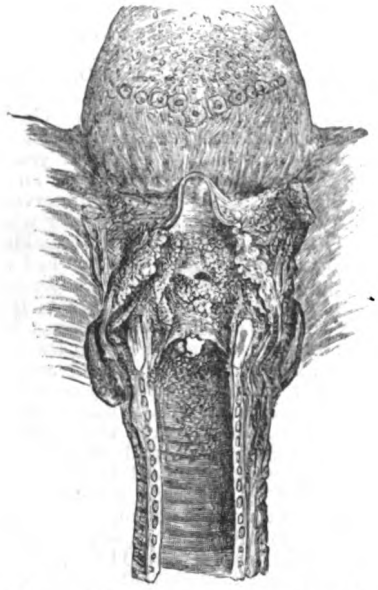
the presence of the tube in the trachea lessened his nervous agitation. To this he gradually accustomed himself, and little by little also he learned to sleep with the tube corked. Meanwhile his throat was sprayed with astringent applications, and the sub-inflammatory condition at last subsided; the boy also grew considerably. Finally, after many failures, we succeeded in removing the cannula; but his inspiration continued noisy for many months, though it had ceased to be laboured. His general treatment consisted in a liberal diet, with cod-liver oil and steel wine.

In many similar cases which I have seen at various times the nocturnal exacerbation of symptoms has occurred; the crisis is reached between two and three o'clock in the morning; the difficulty then appears to have expended itself, and comparative ease and quietness follow.

(*b*) *Warty Laryngitis* (*Papilloma*).—Dr. M. Mackenzie, in his work on the Larynx, p. 300, says, "Chronic congestion of the laryngeal mucous membrane is, far above all other causes, the most important etiological feature in the production of simple morbid growths in the larynx." In the following two cases there was no very manifest cause, but the social surroundings of the patients were just such as would favour the onset of chronic catarrh in children with a predisposition thereto. I am inclined to attribute greater weight to personal predisposition than to chronic congestion, which is itself a morbid condition. Among poor children chronic laryngeal catarrh (chronic congestion) is common, while warty laryngitis is very uncommon. Warty laryngitis is occasionally congenital; I have myself seen one or two instances in the bodies of children who have died of other complaints, and before the local condition had had time to manifest itself.

CASE 4. *Laryngeal Catarrh; increasing Dispnœa; Tracheotomy; Warts seen on Vocal Cords through Tracheal Wound; perfect Relief by Operation; Pneumonia three months later; Death; Autopsy.*—W. C——, aged twelve months, was a small, careworn-looking child when he first came under observation. The mother's account was that

FIG. 3.

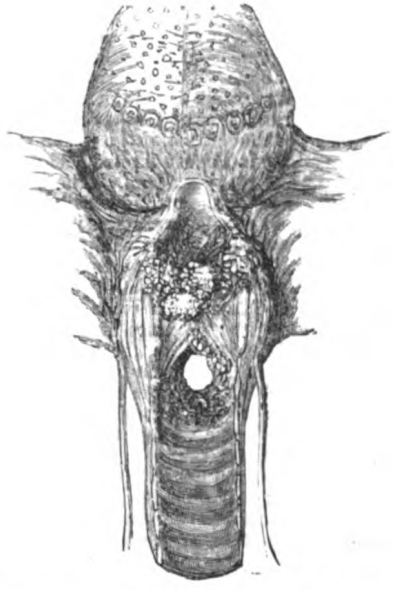


the disease began nine months previously, when the child was between three and four months old; she thought he had caught cold. This was followed by wheezing. Six months ago (at Christmas time) the child lost his voice, his cough became croupy, and he began to breathe with stridor. This stridor gradually became more marked, and during the last four months it had been so bad during the night that the child had only been able to sleep for very short periods during the whole of this time. There was no history of phthisis nor anything reliable of syphilis. When first seen he was greatly emaciated and looked exhausted. The child seemed drowsy and tried to sleep, but the difficulty of breathing roused him at once. The breathing was very laboured and stridulous, the cry almost inaudible. With each inspiration there was recession of the epigastrium and of the episternal region; expiration was comparatively easy. The fauces were congested; the tonsils also, but not enlarged. The skin was of a livid pallor. The child was put into the croup-bed, and steam, with creasote vapour, was turned in. There was no amelioration; on the contrary, at five o'clock in the morning, the breathing having become exceedingly laboured, tracheotomy was performed. The relief was immediate and complete. On examining the trachea through the wound, held open by double blunt hooks, a crop of sessile warts could be distinctly seen on and about the vocal cords. A cannula was then put in, and the child returned to bed, when he slept soundly for some hours. Within a few days general improvement set in. He could now sleep well, and he now took food with relish; the wound in the neck healed well, save a channel for the tube, which we did not even try to remove under the circumstances. For two months the child throve; then he got pneumonia and died rapidly.

In this case the history pointed clearly to a chronic condition, and all doubt as to its real nature was set at rest by the examination of the larynx at the time of the operation. The child was so young and so small that the question of thyrotomy was only entertained to be discarded, for apart from the serious nature of the operation, the scattered sessile condition of the growths would have added materially to the difficulties of the operation. The condition of the larynx, as found after death, is depicted in Fig. 3. Microscopically these warts were found to consist of delicate nucleated fibrous tissue. Our attention was chiefly directed to the general health, which had suffered very much from want of sleep. We were especially careful to provide him with a well-fitting tube. This was changed from time to time, sometimes a long tube, sometimes a shorter one, being used. As will be seen, there was no ulceration from the tube below, but above a quantity of granulation tissue had formed itself into something like a membranous diaphragm which easily broke down when touched.

Another case of papilloma of the larynx came under my

FIG. 4.



observation quite recently. The history of the case differs considerably from the last; the child was older, but the exact nature of the obstruction was not made out until after death.

CASE 5. *Chronic Laryngitis; progressive Stridor; Dyspnœa; Tracheotomy; Measles three months later; Death; Autopsy: Papilloma of Larynx.*—Annie D——, aged three years and a quarter, was admitted into the East London Hospital for Children in November, 1882, under the care of my colleague, Dr. Donkin, with a history "that she was well one day and her voice gone the next." The condition of the voice was slowly getting worse week by week, but she was not ill in herself. On admission, the breathing was stridulous and the voice hoarse; there was recession of the soft parts of the anterior part of the chest. The tonsils were very large;

they almost met in the middle line. The diagnosis was chronic catarrhal pharyngo-laryngitis. Every kind of treatment, both local and constitutional, was tried for some weeks without any good effect; her voice gradually became weaker, and her dyspnœa more severe. During an attack of pneumonia, from which she suffered in the following February, her dyspnœa became so urgent that Mr. Battams, the resident medical officer, had to perform tracheotomy. She went on well and seemed relieved of all her dyspnœa, but the voice in no way improved. Many attempts to remove the tube were made, but were unavailing. In process of time she was got up and allowed to play about the ward, and in suitable weather she went out into the garden. In May she caught measles, which was then epidemic in the neighbourhood, on which broncho-pneumonia again supervened, and she died on May 26th, still wearing her tracheotomy tube. The autopsy revealed extensive pneumonia, and the condition of the larynx is depicted in Fig. 4.

It will be seen that there are two large cauliflower-like warts on the left vocal cord, with a crop of smaller warts on the right cord, and scattered about the larynx generally. There were some small flabby granulations around the inner orifice of the tracheotomy wound, but no ulceration in the trachea.

In this case a correct diagnosis would have been of interest, and possibly of service, but the history was insufficient for the purpose; the condition of the tonsils and pharynx generally precluded the use of the laryngoscope, even had the age of the patient not done so to any but such skilled laryngoscopists as Mackenzie or Semon. But a diagnosis might probably have been made from the tracheal wound at the time of the operation had the attempt been made. It is even possible that the warts might have been snipped off; at any rate, the larger warts, which were more or less pedunculated, could have been removed without much difficulty. It is of course doubtful whether the smallest ones could have been removed, but it is equally doubtful whether they were present at the time the tracheotomy was done. I am inclined to think that they may have grown subsequently in response to a long-continued irritation of a mucous membrane with warty proclivities. Such cases, when they can be diagnosed, should be taken in hand at once. Nothing is gained by waiting: the warts spread, they grow larger, and every subsequent operative interference beyond the first one adds to the dangers and uncertainties of the case. If the diagnosis of warts in such a case as the foregoing can be made with certainty, an attempt to remove them one way or another should be made. Since writing this, a case has come under my care in which I have performed thyrotomy, and removed an immense crop of warts filling the interior of the larynx. The child has done well; she is still under care.

(To be concluded.)

SMALL-POX HOSPITALS AND CAMPS.

By R. PRINGLE, M.D.,
LATE OF THE SANITARY DEPARTMENT H.M. BENGAL ARMY.

As there appears to be a very great variety of opinion about the effects of small-pox hospitals and camps on the health of the residents in their vicinity, and in consequence of this on the value of the property adjacent, it may be useful to draw attention to that which, as far as my perusal of the evidence in the Darenth small-pox hospital case, and the letters in the papers regarding the small-pox hospital at Hampstead, and its effects on the neighbourhood, enable me to judge, does not seem to have had that importance attached to it which a thirty years' practical experience of the subject in India would lead me to expect it should claim. I allude to the infection spread by means of the small-pox crusts or scabs. To those who have not seen inoculation as practised from time immemorial in one of its Himalayan homes—viz., the independent native state of Tirri Gharwál—the recognised value of small-pox crusts, not only in producing the disease by inoculation, but in conveying the virus, or infecting matter, from the plains of Hindostan to the Himalayas would be almost incredible, and the way in which the small-pox matter in these crusts retains its vitality, notwithstanding its unprotected exposure to the heat of the tropical sun in June, and the want of either care or method in conveying it during a journey it may be of weeks, in my opinion shows most clearly the very important part these crusts play in the propagation and dissemination of small-pox.

I have no wish here to forestall a paper on the subject of inoculation which I hope to be able to read in May before the Society of Arts, on "The Ancient and Modern Methods of Treating Epidemics of Small-pox in India." Suffice it to say, that it is only the dried matter, as contained in the small-pox scab, which the Himalayan inoculators have used from time immemorial to inoculate with in the following manner. This small-pox scab is powdered down and mixed with a kind of treacle and flour, and applied externally on a surface denuded of skin by means of scratches made by sharp needles embedded in wax, fastened together by blue thread, while, if the supply of this compound is sufficient, a certain quantity is also given internally in the form of pills. When practising vaccination and introducing the prophylactic twenty years ago into these homes of hereditary inoculation, for similarity of operation, with, I need hardly add, the exception of the internal administration, I used vaccine lymph, or matter in the dried state, and then undoubtedly learnt by analogy the very important part these small-pox crusts must play in diffusing the infection of small-pox. To those who have closely studied the subject the very construction of the crust or scab in small-pox seems intended for its diffusion, like the small seeds surrounded by a light tissue substance, which aids greatly in their dissemination by means of the wind alone, and thus the very opening and shutting of a door in a small-pox hospital may blow away a certain number of small-pox crusts into corners and places where they may entirely escape observation, the dried lymph of which may be in a very small quantity, while the surrounding thin tissue of skin may be so considerable as, as in the case of the seed, to enable it under certain conditions almost to float in the air. All that is now necessary is moisture to induce this lymph to germinate, and this is readily obtained in the fluid exuding either from an abraded surface or when taken into the system and meeting with the moisture covering the various suitable internal mucous membranes of the body. This clear dried-up lymph readily powders under friction in a pestle and mortar, and so fine is the powder that it cannot be done with safety except by the aid of water or in a room free from draughts. I have put this to the test of practice in my numerous attempts to inoculate cows and calves by means of fluid lymph and the dried small-pox crusts, in the hope of producing artificial vaccinia, an account of some of which trials can be found in THE LANCET of Jan. 28th, 1882, and June 3rd, 1882.

Now, small-pox crusts are very different from the generality of vaccine crusts, being much smaller and lighter, and, notwithstanding every possible precaution, who is to limit the distance to which some of these crusts may be carried by the wind alone? and when once crushed, even by the foot, who is to tell where this fine powder may not find ground suitable for germinating in? for we must remember the smallest quantity of this powder is quite as active as the clearest and freshest lymph under certain conditions, the chief of which is moisture. As previously noted, no ordinary heat, such as exposure to the unprotected sun's rays in India, destroys the vitality of the germs in this small-pox virus; but excess of moisture in a tropical climate decomposes it to such an extent as to make it innocuous. This can be illustrated by the following, a fact I pointed out some years ago, and recorded in my official reports—viz., that a deficient rainy season in India produced an early and extensive recrudescence of the annual small-pox appearance, by withholding the extra moisture which by decomposition destroys to a very great extent the virus thrown broadcast over the country in the form of these small-pox crusts. Thus, for instance, after an unusually deficient rainy season in India small-pox often becomes epidemic in November, instead of dying out in September, not to be sufficiently revitalised till May. With vaccine lymph the case is different; the heat to which a postal letter-bag is subjected in transit in the plains of India, or when lying on the road-side, from March to October every year, will destroy the activity of the vaccine lymph, unless specially protected by cotton-wool in wooden, not tin, boxes, and despatched in the evening. Now, what are called cycles of small-pox epidemics may thus be traced to the dryness of the season, and the present increase of small-pox in London may be due to this circumstance—viz., the limited rainfall of 1884.

As regards the various stages of small-pox in their relation to infection and contagion, my practical experience has satisfied me that to the fourth complete day, or when the character of the disease is clearly defined, the case is innocuous; and that under any condition, there is only infection in its strict meaning, either when the small-pox virus is in the clear moist state, as seen in the vesicle, or else in the dry state, as seen in the crust or scab. In the former it is at once admitted into the system by means of its own moisture; in the latter it requires moisture from without, and a certain amount of friction to reduce it to powder; or, in other words, the really dangerous period to the public health is in the scabbing stage; the vesicular stage, or that when the contents of the eruption are clear, is after the fourth or fifth day of the eruption, a period no doubt of infection and contagion, but then only within the immediate proximity of the patient, and under peculiar conditions. Till the eruption of small-pox contains a fluid capable of extraction by puncture, and of imparting the disease when inserted by inoculation, it is surely unreasonable to suppose that without this extraction any substance can be evolved from the eruption which could produce and spread the disease by either contagion or infection. Now, the earliest period at which fluid is capable of extraction from the eruption is never met with, even in India, before the complete fourth day; therefore the case till then is innocuous.

As regards the activity of the matter in scabs, according to my experience vaccine operations performed with the clear dried lymph, or matter in the centre of selected vaccine crusts, are as successful as those performed with the clearest vaccine lymph of the sixth or seventh day; but I need hardly state that, except in the instance given, when introducing the prophylactic I would never think of using the virus in a crust when that from a good vesicle was obtainable. As regards small-pox virus, however (if I except the heat generated in a disinfector), the only condition in which its vitality or activity is destroyed is, as pointed out, in the case of an excess of moisture, which appears to effect this result by decomposition; virus, however, naturally stored in the scab, and hid away in a dust heap secure from this moisture, will keep active for months, even in India; but then, in an ordinary rainy season, this protection from rain can only be secured by a limited number of scabs, so to speak; and the resulting sources of contagion being thus very limited, the spread of the disease is equally gradual, until a few cases occur, when the contagion and infection increase in a proportion out of all comparison with any other known similar disease, and this rarely occurs till May or June. In an unusually dry season, however, an increased number of these scabs having escaped this process of decomposition when the weather becomes sufficiently dry to favour their powdering, as it does in October, they become powdered, and the infection and contagion are at once lighted up; and what is termed a cold weather epidemic of small-pox is witnessed, or one that reaches its height in December instead of June. I enter into these details as they are the result of twenty years' practical experience and observation of a country larger than Great Britain, with a population of ten millions, and they may perhaps throw some light on the causes of the late epidemics of small-pox in London.

In 1883 some small-pox crusts, which got mixed with the sugar swept up from the floor of a native sugar factory, and carried by hill men from the plains of Hindoostan to close under the snowy range of the Himalayas, were the cause of an outbreak of small-pox in one of my vaccine lymph nurseries, among the children kept for collecting vaccine lymph for originating vaccine operations in the plains. Vaccination soon stamped this out, as every unvaccinated child was vaccinated, and neither revaccination nor a small-pox hospital were thought of. So satisfied am I upon this point, after having seen the rapidity with which an epidemic of small-pox reaches an alarming height, that I should unhesitatingly state that the worst method of meeting or treating an epidemic of small-pox (except under the condition I give hereafter) is to establish large hospitals or camps anywhere near crowded localities, and the more open and exposed the sites the more chance of the disease spreading. There is only one way to meet and defeat a small-pox epidemic—i.e., by careful and systematic vaccination; and here I speak not from theory, but from repeated practice, and the facts are public property, and can be referred to at any time in the records of the Agra and Meerut divisions of the North-West Provinces during the past twenty years. By careful and systematic vaccination I mean a system of vaccination so universal as to nearly reach the birth-rate, and so careful as to require no revaccination. If small-pox appears among a community reported to be thus protected by vaccination, the fault will be found to lie either in the veracity of the returns or the quality of the vaccine operation. Here again I speak from facts, not theories. In the district of Jalaon in the North-West Provinces, with a population of 380,000, the recorded number of vaccine operations over a series of years sufficiently nearly reached the birth-rate to expect an immunity from small-pox, and yet the disease could not be said to be expelled from this district, as there were yearly many deaths from small-pox. When this district came under my supervision, I at once felt assured that this was due to one of these two causes, judging from the experience of the Dehra Dun district, with a population of 150,000 (and the Military and Civil Sanatoria of Mussoorie, Landour, and Chuckrata in the Himalayan portion of it), where not a single death from small-pox had been recorded for years, and if the disease subsequent to this time appeared at all, it was confined to isolated unvaccinated cases. A careful and impartial inquiry into the system of vaccination in the Jalaon district exposed a system of vaccination on paper to an almost incredible extent, and the exposure in this led to inquiries in other districts in the North-West Provinces and Oudh, when in the second circle, with a population of 17,000,000, a system was laid bare which the Government of India described as a "wholesale fabrication of returns," sufficiently accounting for the terrible mortality from small-pox witnessed in 1882-83. I will, however, do the Government of India the justice to state that, though at first this "vaccination on paper" led to the unusual and rapid promotion of those responsible for it, yet on all the facts becoming known the retirement of the officers concerned alone prevented further proceedings being taken.

Let me illustrate the difference between "vaccination on paper" and vaccination on the arm in the district of Muttra in the North-West Provinces. From 1859 to 1861 vaccine operations by thousands were recorded in the published returns of this district, but, notwithstanding this, in the end of 1863 small-pox in the city of Muttra alone, with a population of 44,000, carried off in two months 3500 children. This fact the recording officer assured me of. In the cold weather of 1882-83, a period of most unusual small-pox prevalence, not one fatal case of small-pox occurred in this city; but here for twenty years I have been practising vaccination without either revaccination or small-pox hospitals. It is in no spirit of self-laudation I make this comparison, but simply to point out the worthlessness of vaccine returns which exhibit results which facts fail to support. I do not for a moment question the veracity of the returns in London, for instance, as likely to show a cause for the present epidemic of small-pox among a population the birth-rate of which is sufficiently protected by recorded vaccination to warrant the expectation that small-pox will be excluded, but, judging by analogy, I cannot help questioning the quality of the vaccination, as I must state that I have seen in a small-pox hospital in London what I have never seen in my circle in the North-West Provinces in India, with its ten millions, during the past twenty years—viz., a hospital of upwards of sixty beds filled with cases of severe attacks of small-pox in many instances following vaccination, which I should most certainly have credited with an immunity from small-pox equal, if judged by the vaccine mark, to that which has carried me safely through small-pox epidemics such as one knows nothing of in this country. Here, in my opinion, lies the whole point at issue. How is this possible? and how is this seen in London with, after all, really its limited area of infection and contagion, when compared with my circle, and where for the last twenty years I have never revaccinated a single native, and discouraged the practice among my two hundred subordinates? Nor need this discouragement be wondered at, for, independent of my not understanding the reason professionally for the operation, in most of the localities in my circle not half the birth-rate was reached by a primary vaccine operation; it seemed to me, therefore, a positive waste of time, lymph, and money, and an inducement to false returns, which the inquiry alluded to fully proved, to go over the work of previous years. My facts relating to this immunity are drawn from what I may term isolated areas of protection surrounded by small-pox contagion

and infection, such as it is impossible to convey any idea of.

It is not the object of this paper to discuss in detail the system of vaccination I adopted, but merely to draw attention to the effects of small-pox hospitals on the health of the locality. The only conditions under which I should consider the collection of cases of small-pox into a hospital justifiable are those met with in localities where vaccination from climatic reasons is not practicable at the time, and with the following instance I will close:—

In 1863, while in medical charge of a battery of Royal Horse Artillery at Morar Gwalior, some cases of small-pox were reported soon after the arrival of the camp of the second Captain of the battery, who had joined from Saugor. I obtained permission to treat these cases in an isolated locality, and collected all I could hear of and had them brought to this hospital tent. They were all admitted before any infection or contagion could be developed (as noted before) by them, either in the localities in which they occurred or those through which they passed to the hospital. The cases (seven in all) were gathered from every quarter of the cantonments, and not another case occurred. The outbreak was thus effectually checked; and, as if to show the success of this mode of treating, and I may add defeating, the disease, the next year these precautions were neglected, and there was not a regiment in the cantonment which did not suffer from small-pox more or less; while numbers of camp followers and residents in the regimental bazaar, on the appearance of the disease, left the cantonments and passed into the native State of Gwalior. The Government, to whom my report was submitted, evidently approved of it, as my suggestions embodied in that report were copied almost *verbatim* into the Government Orders, and are now the standing orders on the subject of the treatment of cholera, small-pox, and similar epidemics. I trust I may not be thought to write too confidently on the subject of vaccination, but after seeing the tests my work of twenty years has successfully stood, and knowing as I do that every successful case of vaccination in a native village has to stand annually an amount of small-pox contagion and infection, which it is difficult to understand in this country, I feel I should be wanting in my duty as a medical officer if I failed to bring this prominently before the public. I am aware that small-pox hospitals are looked upon as a nuisance and tolerated as unwelcome necessities; but with the greatest deference I cannot help viewing them as the worst method of treating a small-pox epidemic, and if they are not necessary in large cities like Meerut and Muttra in India, or districts like the Dehra Dun, it is certainly worth while inquiring into the circumstances which make them necessary in London.

Blackheath, S.E.

ON THE

TREATMENT OF ADHESIONS OF THE IRIS TO THE CORNEA.

BY GEORGE E. WALKER, F.R.C.S.,

SURGEON TO ST. PAUL'S EYE AND EAR HOSPITAL, LIVERPOOL.

THIS is a subject to which I have given a good deal of attention for many years; and as I have come to look on nearly all cases, even of the most extensive adhesions, if only there be any anterior chamber at all, as susceptible of successful treatment, I venture to offer a few instances of the worst sort for consideration. It is notorious that a very small adhesion of the iris to the cornea renders the eye useless—that is, of course, if the other eye be sound; but if, as occurs in many cases, the other eye be destroyed, the eye is so impaired as to render its possessor a fit inmate of a blind asylum. Yet when the other eye is sound it may be so irritated by the damaged eye as to be rendered of much less use than it ought to be, as in the case of a boy whose education was stopped because whenever he attempted to read, the damaged eye, which had a small pointed synechia very near the centre of the cornea, began to ache and to water, in which action it was speedily joined by its fellow. The division of this adhesion relieved him of all his distress at once. But where it does not cause such active distress as this its influence is bad enough. In a case of similar adhesion occurring in a young man, who had probably passed through such a probation in his childhood, after the division of the synechia, he said, "Before I could only see shadows; now I can see as well as with the other eye." I have at present under my care at the Blind School a young man of about twenty who has one eye totally destroyed, but the other has merely a pointed synechia near the centre of the cornea; the sight is so impaired as to render him incapable of getting his living as a sighted person. I have been unable to induce him to let me relieve him of his embarrassment.

I have selected the following two cases because they appeared to offer the most formidable difficulties in the way of relief:—

A young lady, Miss M——, aged eighteen, came to me on February 16th, 1884. She had extreme divergence of the right eye, and about half the iris was attached to a vertical scar a quarter of an inch long on the inner side of the cornea at about one-eighth of an inch from the edge. She could make out 30 Snellen by putting the letters close to the eye. As her health was not quite satisfactory I postponed the operation till April 3rd, when I thrust a narrow knife through the outer edge of the cornea at the horizontal meridian, getting the point as far under the lower edge of the synechia as I thought I should be able to cut; I then used the knife lever-wise, cutting upwards. In this case I used eserine several times before operating, so that the iris was completely taut, and after the operation atropine with great frequency. Next day, when the pupil was dilated, it was found that a very considerable portion had been freed by the incision, and the pupil was much larger. There was little reaction, and on the 17th I attacked the upper part of the adhesion in a similar way, this time, of course, cutting downwards, with a still further gain of pupil. There was after this also little reaction. The pupil dilated now, so that one could see that the lens was absorbed, leaving the capsule fairly transparent, with the exception of a white bar of opaque membrane running almost vertically across the pupil. On May 7th I performed a larger operation to sever the iris running between the scar and the inner edge of the cornea. This was obviously a matter of greater difficulty than that of severing the upper and lower part of the iris, for the latter could be put upon the stretch either by eserine or atropine; indeed, when unaffected by drugs it was on the stretch, therefore separable with comparative ease, whereas that going from the inner edge of the ciliary region to the vertical scar was slack and incapable of being stretched. I used eserine, but I think it did not help at all. On this occasion I operated differently. I fixed the eye at the inner horizontal meridian, and thrust the knife through the cornea at the lower point of the vertical meridian, then, passing the knife between the scar and the inner edge of the cornea and using it lever-wise, stretched the iris without cutting it, until the point of the knife almost touched the outer edge of the cornea. It was astonishing to see the iris, which seemed to be so narrow, stretch completely across the eye, as a thin bluish veil. When the point of the knife had arrived at the end of this great traverse, I was aware of the iris snapping, but as the aqueous escaped at the same time as I was engaged in getting the knife out of the eye without doing any damage, I did not see how much I had cut; but Mr. Moir, who assisted me, said that there was a great triangular pupil formed. The anterior chamber at once filled with blood, so that it was impossible afterwards to see how much had been accomplished. Of course such an extensive interference with the ciliary region as was involved in the dragging of the inner quarter of the iris across the eye was followed by a serious reaction; yet two leeches in the evening stopped it, and with the aid of mercurial inunction the pain ceased, and the blood was absorbed; whilst in two or three days after the operation it was seen that the whole of the adhesion except a small band at the upper end of the scar was severed. For some time there was no red reflex, so that it was impossible to see what had taken place behind the iris; but the media gradually cleared, and then it was seen that there was a delicate veil-like opacity floating just behind the scar. On May 28th she made out Snellen 15, and later 8. But as my patient has not got central fixation, it is to be feared that the improvement to be expected is rather in the appearance of the eye than its use. It is obvious that had the synechia been divided soon after the injury the eye would have been as useful as a lensless eye can be.

Now, this case of peripheral synechia is one of the most difficult to treat when left alone for a long time. The iris is

not on the stretch, but, on the contrary, is folded on itself. It atrophies, for it is never used; whereas the iris when attached to a wound near the centre of the cornea is always on the stretch. But attacked early, these peripheral adhesions are by no means difficult to treat, as will be seen by the following case.

A. B——, aged forty-two, was struck on the eye by a piece of metal, which produced a wound of the cornea, beginning at the outer edge at a point midway between the horizontal and upper extremity of the vertical meridian and extending vertically downwards below the horizontal. In this the iris was engaged. I tried to thrust this back by pressing it through the wound with the back of a knife, but in vain; so waiting a few days, I operated as I did in the case of Miss M——, thrusting the knife from below, insinuating it between the wound and the outer edge of the cornea, and then pressing the iris towards the centre. The iris was disengaged from the wound without being cut; the lips of the wound closed without escape of aqueous; and, with the exception to be noted, all soon became well. The exception was this: I found, a few days after the operation, that although all the pupillary edge of the iris was free from the wound, a little of the outer part of the iris was engaged in the upper end of it. However, the man found his eye quite free from trouble; he apparently did not share my anxiety to polish the matter *ad unguem*, for a hint at further interference was followed by his ceasing to attend. This "stroking out" of the iris without cutting seems to be a very valuable addition to our therapeutics, but its applicability is limited. I tried it soon after in a case which I shall next describe; but the eye was not stiff enough, for the attempt simply caused it to "buckle."

A boy, aged twelve, came with a wound of the cornea and sclera extending from a little outside the centre of the cornea in the horizontal meridian to a point about a line from the edge of opaque tissue. The iris was engaged in the whole length of the wound, and the lens was also cut. After the failure of the attempt I waited until the eye became firmer, when I operated as in the case of Miss M——. The attachment was so tough that nine operations were required for the complete severance of it. But the result well warranted the procedure, for every particle of iris was separated from the scar. As I have mentioned above, I tried to stroke out the iris, but there was not sufficient stiffness in the eye to afford counter-resistance. I now come to the last of the cases, one of which, I think, deserves to wind up the series.

A young gentleman, aged nine years, was brought to me by his mother on Feb. 18th, 1884. She stated that three years before he had accidentally been stabbed in the eye with a pen. I found a starred scar in nearly the centre of the cornea, to which all the iris, except enough at the lower and inner part to form a pupil, after free use of atropine, as large as a pin prick. The upper and inner quadrant of the edge of the cornea was so flattened by the piece of the imprisoned iris that at first sight the eye seemed hopeless. But I found after a prolonged examination that he managed with much oscillation of the eye and movement of the paper to make out No. 200 of Snellen, and I therefore decided to attempt to save the eye instead of advising its excision, as at first I was inclined to do. On the 23rd, assisted by Mr. A. Moir, after using atropine freely, I chloroformed the patient deeply, and then fixing the eye at the upper and outer part, thrust through the cornea at its outer edge, a little below the horizontal meridian, a narrow knife, fresh from the cutler, between the iris and the cornea, until the point was well beyond the inner edge of the adhesion; then by raising the handle and using the knife lever-wise depressed the blade against the tightened iris. To my delight the whole of the iris, except a minute bit at the lower and and outer part, which indeed could not be influenced by the knife in this position, gave way. Atropine was freely used afterwards. The eye gave little trouble, although the boy suffered a good deal from the effects of the chloroform. This was due to his digestion being deranged, but the treatment to which he was subjected for this enabled him to bear three subsequent chloroformings without any trouble. He had now, instead of a pinhole pupil, a good sized one, and on March 6th, with a $2\frac{1}{2}$ + he made out a few of the letters in 20 Snellen. By this time we could see that the lens had been wounded, as indeed we had inferred. He was then sent home. On March 21st he read 15 Snellen, and on that day I divided the remaining bit of iris, using the knife as before, excepting that the eye was fixed below, and the knife made to cut upwards. The pupil further dilated, and the reaction was so small that he was able to go home on the 27th. On April 17th he could spell 1·5 Snellen. I now could get a thorough examination of the pupil, when I found this condition:—After the first cut the inner central part of the iris had fallen on, and adhered to, the capsule of the lens; but that the upper was free. From the outer edge a filament of brown tissue extended to the scar. How this came about I cannot be certain; but I imagine the aqueous escaped, after the last operation, during retching, and that the edge of the iris became attached to the scar for a short time, and then receded as the aqueous was restored, leaving the spider-like thread of uveal exudation. I wished at the next operation to divide this, and to cut the capsule; but the knife was bad, and let out the aqueous as soon as I used it lever-wise. However, I found that I had divided the filament, and although I had not cut the capsule, I had disturbed it so as to let the pupil dilate considerably. On the 22nd his vision was $\frac{1}{18}$, and on the 29th $\frac{1}{24}$. On May 14th I made an incision in the capsule, and got a good-sized pupil, the operation causing no shock to the eye; on the 19th his vision was $\frac{1}{6}$ m., and Jaeger 1, and on the 24th $\frac{1}{5}$ m. Of course this case is exceptional, and one must expect few of such brilliancy. I think, however, I have shown that it is possible to give relief in a class of disease the formidable nature of which was well summed up by an ophthalmologist of the very highest repute on the Continent, who in reply to my telling him that I was in the habit of dividing anterior synechiæ, said, "You had better leave them alone; you will do more harm than good."

Finally, in performing these operations it is necessary to bear in mind these two axioms: first, you must make your corneal puncture at such a point as will afford the greatest sweep of the knife; and, second, that you should so manage the heel of the knife as to cause no loss of aqueous until the adhesion is severed. It is not always easy to decide beforehand whether a myotic or mydriatic should be used. One would think that for a central adhesion a mydriatic would be always the best, but in one case I failed twice to cut a central adhesion under the influence of atropine; whereas in a third attempt under eserine it gave way at once. Another point: the knife ought to be fresh from the cutler. I seldom attempt more than two or three such operations with one knife, which of course afterwards will do quite well for operations of inferior delicacy.

Liverpool.

CHRONIC CARDIAC ANEURYSM.

A CASE OF ANEURYSM OF THE WALL OF THE LEFT VENTRICLE AND OF THE MITRAL VALVE IN THE SAME SUBJECT.

BY HENRY HANDFORD, M.D.

I MET with the following case in the post-mortem room of the General Hospital, Nottingham, in July, 1883. The patient had been admitted a few weeks previously under the care of Dr. Brookhouse. He was an iron moulder by trade, and had led a "roaming wild kind of life." There was no distinct history of syphilis or of rheumatism. He was thirty-six years of age, and was not aware that he was in any way ill till about a year ago. He had only been unable to work for about ten weeks. He had great dyspnœa, and œdema of both legs and of the scrotum, which latter was twice tapped with Southey's trocars and about twenty fluid ounces removed on each occasion. He had a systolic mitral murmur and a double aortic one. The diastolic aortic murmur was conducted best down the sternum and to the left, but was not heard at the apex. He complained occasionally of præcordial pain, but not very specially. He was only passing sixteen ounces of urine daily on admission, but the amount gradually increased up to forty-six ounces. He seemed to be improving considerably, but died suddenly in the night of July 2nd, 1883.

Necropsy, twelve hours after death.—Rigor mortis slight. Head, neck, and shoulders very livid. The pericardium contained about four ounces of clear straw-coloured fluid. There was a milk spot about the size of a shilling on the anterior surface of the right ventricle. Fibrinous, partially decolourised coagula were found in the cavity of the right ventricle and in the pulmonary artery. The clot in the pulmonary artery was not adherent to the walls of the artery.

There was a very small coagulum entangled in the mitral valve. The aortic valves were incompetent. The weight of the heart after it had been opened and its cavities thoroughly washed was twenty-eight ounces. The aorta was dilated and atheromatous, one or two patches becoming calcareous. The latter change was evidently only just commencing. The left anterior segment of the aortic valve was much thickened and indurated. The other two segments were not much altered. Between the left anterior and the posterior segments of the aortic valve, just at the base of aortic segment of the mitral valve, was a rounded opening, with a sharp fibrous margin, about the size of a fourpenny piece. It led into a cavity as large as a small walnut, which projected into the left auricle. The cavity was not lined with fibrin, and its walls consisted of fibrous tissue about one-twentieth of an inch thick. Between the right anterior and the posterior segments of the aortic valve was a circular patch the size of a sixpence, where the endocardium was softened and yellow; this also had a sharp fibrous margin, and was very slightly depressed. This was more evident on passing the finger over it, when the depression and the yielding nature of the patch, with its sharply defined margin, readily suggested a commencing aneurysm similar to the one on the other side. At the left border of the left (posterior or inferior) segment of the mitral valve was the opening of another cavity, very slightly smaller than the first, and also projecting into the left auricle. It had a prolongation into the left ventricle between the cusps of the mitral valve, and this prolongation had ruptured, and had a small, smooth opening at the extremity. It seemed to be an aneurysm of the posterior segment of the mitral valve, which had projected in two directions—both into the left auricle and into the left ventricle,—and the latter portion had given way. The aneurysm of the wall of the left ventricle, which I have already described, and which projected into the left auricle, was not ruptured, neither had the portion of the aneurysm of the mitral valve which projected into the auricle ruptured. Thus, there were two sharply circumscribed, rounded and tuberculated swellings projecting into and partially filling the cavity of the left auricle. The endocardial lining of the left ventricle and of the left auricle was much thickened, that of the right ventricle only very slightly so. The fossa ovalis was very deep, and a very oblique opening existed into the left auricle, through which a probe could be passed. The right ventricle was much dilated and hypertrophied. The columnæ carneæ were very numerous and prominent, and the heart muscle between the reticulations had in many places almost disappeared. At the apex of the right ventricle the cardiac wall was barely one-twelfth of an inch thick, and consisted of thickened pericardium and fibrous tissue lined by the endocardium, with scarcely a trace of muscular structure left. The columnæ carneæ in the left ventricle were unusually numerous, and many of them were reduced to mere fibrous cords. There was one two inches and a half long, attached at both ends and free in the middle, passing from the upper part of the anterior wall of the left ventricle towards the apex, and as thin in most of its course as a thread of ordinary sewing cotton, but still quite firm. Another, somewhat like it, was an inch and a half long. Both of these were on the anterior wall (septum) of the ventricle, near the commencement of the aorta, and in a part otherwise quite smooth and free from columnæ carneæ. The left auricle was considerably hypertrophied and dilated, as was also the left ventricle. The tricuspid valve was normal, but the auriculo-ventricular opening was dilated. The pulmonary valves were normal. The lungs were congested, and in a state of brown induration. The liver weighed seventy-two ounces, and was markedly in a condition of cyanotic atrophy. The gall-bladder was small, and nearly empty. The spleen was very firm, much indurated, and weighed nine and a half ounces. The kidneys were very hard and firm, the capsules very slightly adherent; surface pretty smooth. On section they were seen to be much congested. The cortex was not diminished in extent. The pyramids were very dark. The left kidney weighed eight and a half ounces, the right eight ounces.

Remarks.—The condition of the aortic valve was a satisfactory confirmation of the observation of the direction of propagation of the diastolic aortic murmur, according to the views expressed by Dr. B. Foster in his "Lectures and Essays on Clinical Medicine," page 127—viz., that an aortic diastolic murmur, propagated to the heart apex usually means incompetency of the posterior (or mitral) aortic segment; and that an aortic diastolic murmur propagated down the sternum towards the ensiform cartilage indicates incompetency of either the left coronary or the right coronary segment, by which the regurgitated current is thrown more upon the septum of the ventricles. The systolic mitral murmur is sufficiently explained by the aneurysm of the posterior segment of the valve, but more especially by the projection between the cusps of the valve of the prolongation of the aneurysm as described above, so preventing the valves closing properly and rendering them incompetent. It is doubtful whether the aneurysm of the wall of the left ventricle gave rise to any murmur, and if it did what its rhythm was. There was no murmur detected during life which could not be accounted for by the condition of the valves found post mortem. I should expect the aneurysm of the wall of the left ventricle to be filled during the ventricular systole and emptied during the auricular systole, because it projected into the left auricle, and would be compressed when the auricular walls contracted; in which case two murmurs might be produced—the one, occurring on the filling of the aneurysm, would be lost in the aortic systolic murmur, and the other, occurring on the emptying of the aneurysm, would be auricular systolic in rhythm; but no such murmur was detected during life. The aneurysm of the mitral valve, as it had ruptured at one part, would allow a free reflux of blood through it into the left auricle during the ventricular systole, and would, no doubt, give rise to a murmur which would form part of the mitral systolic murmur heard during life.

Nottingham.

THE FROG'S BLADDER AS AN OBJECT FOR THE STUDY OF THE EMIGRATION OF WHITE BLOOD CELLS.

By T. MITCHELL PRUDDEN, M.D.,

DIRECTOR OF THE PHYSIOLOGICAL AND PATHOLOGICAL LABORATORY OF THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

THE vigorous remonstrance of Mr. T. Wharton Jones, in a recent number of THE LANCET, against the belief in so well-established a phenomenon as the emigration of the white blood cells through the walls of the capillaries and small veins would seem almost comical to those accustomed to observe and demonstrate it were it not for the evident earnestness and sincerity of the writer. It is not the purpose of this short article to add more testimony as to the occurrence of emigration, since the negative results of a single observer cannot be considered as seriously militating against the actuality of a phenomenon attested to by hundreds of trained workers, who have carefully followed every stage of the process under the greatest variety of conditions. The writer wishes simply to direct attention anew to the bladder of the frog as an object in which every phase of emigration may be followed with an ease and certainty which do not belong to either of the more commonly employed objects namely, the web, tongue, or mesentery, although it may be readily enough seen upon these. The writer's attention was called to the advantages of the frog's bladder for such purposes several years ago by Prof. Julius Arnold of Heidleberg, by whom it was employed for some of his interesting and most important studies on the phenomena of inflammation.

The abdomen of a frog, which has received the minimal dose of curare requisite to secure immobility, is opened by a lateral incision through the abdominal parietes, a little posterior to the axillary line and extending from the inguinal fold up about half way to the axilla. A glass cannula, bent at about one centimetre from the tip to an angle of less than 45°, is connected by a small rubber tube with a Mariotte pressure bottle containing ¾ per cent. salt solution. The tube and cannula being filled with the salt solution, the tip of the cannula is introduced into the anus, carried into the cloaca, and then directed forward into the bladder. In this position it is held by a thread passed through the skin behind the anus and tied around a constriction in the shank of the cannula. The animal being placed on its back upon any frog-plate suitable for irrigation (one of the forms devised by Thoma and modified by Arnold for this purpose is most

convenient), the salt solution is allowed to run in the bladder from the pressure bottle until the former is partially distended and pouches out at the side through the abdominal opening. The bladder being a bilobed organ, it is well to lay a small weight on the abdomen over the lobe which is not pouched out, in order that the salt solution may collect chiefly in the exposed lobe. By careful manipulation serious disturbances of the circulation may be almost entirely avoided. The bladder may be covered, and its superior surface slightly flattened by a thin cover-glass, beneath which a constant stream of salt solution may be carried through a fine pointed cannula connected with a second pressure bottle. Thus the exceedingly thin wall of the bladder, containing an abundance of venous and capillary bloodvessels, and bathed without and within by salt solution, may be brought into view with high power lenses (inversion lenses are readily applied), and with no intervening tissue except the endothelium to interfere with the clearness of vision. Every detail of the process of emigration can here be seen with exquisite distinctness, and, moreover, which for demonstrative purposes is of great importance, emigration commences almost immediately upon the exposure of the organ, often within thirty minutes, and usually proceeds with a vigour and rapidity which are surprising to those who have been accustomed to work with the mesentery, tongue, or web.

Almost the sole drawback to the use of this organ for such studies is the slow movements which it is liable to make owing to the contraction of smooth muscle fibres in its walls. But if the animal be kept well under the influence of curare by sufficiently frequent very small doses of the drug, and if the bladder be kept well distended and the animal covered with moistened blotting-paper, this movement may be so far reduced as to permit of a continuous observation of any selected point for hours. For purposes of instruction, the bladder possesses another important advantage, in that after the inflammatory phenomena have been sufficiently observed the animal may be killed, and the entire body, with the bladder distended to the same degree as when under observation, may be placed in Müller's fluid or diluted osmic acid, and every cell and tissue element hardened *in situ*. It is possible in this way not only to follow every phase of the process of emigration in a particular white blood cell or in a number of these, but also by carefully mapping out the topography of the place under observation to find in the preserved and stained organ from which, after hardening, the portion under observation in the living condition has been cut, the particular cells whose evolutions have been followed during life. Under these more favourable conditions their minute structure may be compared with that of their fellows which still remain within the vessels or sticking in the walls, and also with the nuclei of the walls of the vessels themselves, from which they differ so materially in structure that the two could hardly be mistaken for one another by a competent microscopist. It appears to the writer that in the prevailing *furor* for bacterial investigations, the study of the phenomena of animal cell life is in danger of being neglected; and it is rather in the hope of contributing to the ease and certainty with which these studies may be pursued, than with the purpose of overcoming scepticism as to the actuality of the emigration of the white blood cells, that the above details are formulated.

New York.

VAGINAL EXTIRPATION OF THE UTERUS, TOGETHER WITH RIGHT OVARY, FOR MALIGNANT DISEASE.

SUCCESSFUL CASE.

BY F. A. PURCELL, M.D., M.CH.,
SURGEON, CANCER HOSPITAL, BROMPTON.

MRS. M. A. G——, aged forty, was admitted into the Cancer Hospital on September 15th, 1884. A strong, well-nourished woman, with no family history of cancer, married, and the mother of five children, the youngest four years old. Her illness commenced four or five months since; three months ago she had a small mass the size of the little finger removed from the os by Dr. Archer. She complained of pain at the bottom of the stomach, with difficulty in walking, and suffered from severe losses. The vagina was found occupied by a papillomatous growth attached to the os and left vaginal wall, being excessively vascular; on the slightest digital examination free hæmorrhage ensued. On September 23rd the patient was placed on the operating table, anæsthetised by Mr. Bailey, her legs fixed in the lithotomy position with Clover's crutch, the wire of the galvanic écraseur was manipulated around the base of the tumour, fixed, the connexions completed, and the growth removed without loss of blood. The tumour was about the size of a cricket-ball. Not feeling satisfied that all the disease was removed, for while examining the charred portion my fingers passed through the left wall of the vagina, I decided that the only chance for the patient being freed of the disease was to extirpate the whole organ. With the consent of my colleagues, therefore, I at once proceeded to do so. Withdrawing the hand, the parts were well syringed out with carbolic lotion (1 in 40) and all other antiseptic precautions taken. I now reinserted the hand, and passed it through the rent, pushing the anterior vaginal fornix, and with it the bladder and its peritoneal duplicature, upwards off the fundus of the uterus; gradually the fingers got over the fundus and by a little manipulation it was turned over anteriorly and brought comparatively easily downwards, the round ligament of the left side sufficiently stretched downwards and brought into position so as to pass a double thread around; both were tied, and the stump was clamped with two of Wells's forceps; the parts were cut between with scissors; the left ovary and some pale-yellow omental fat pressed into view. The ovary, appearing healthy, was pushed back, and a carbolised sponge with string attached was passed up to prevent further protrusion. Still drawing down the fundus, the right ovary then presented in a cystic condition, being about the size of a hen's egg; this, tapped and gently drawn down, was followed by its Fallopian tube, along which were seen several smaller cysts. The round ligament now held the uterus; this was tied, the stump clamped and tied, as was done on the other. The uterus and its appendages were held by the walls of the vagina. This I peeled down, and fixing the galvanic wire around severed and released the whole. Free bleeding from several of the posterior vaginal vessels, one very large, gave trouble. The parts were pressed into view by my assistant passing his two fingers into the rectum and everting the posterior vaginal wall. The large vessel was with some difficulty seized with a pair of torsion forceps; four in all had to be applied to completely control the hæmorrhage; these were allowed to remain on. The stumps of the round ligaments were cautiously unclamped, the sponges removed, a glass drainage-tube inserted, a self-retaining catheter passed into the bladder (the parts around the drainage-tube and the four forceps were plugged with iodoform absorbent wool tampons), the crutch removed, the patient's knees tied together, one grain of morphia administered hypodermically, and, after an operation lasting one hour and a half, the patient returned to bed in the general ward. The peritoneal torn edges were not brought together; all antiseptic precautions were taken excepting the spray; the uterus was removed with the peritoneum intact over its fundus; the ureters and trigone of the bladder were uninjured; all disease of the walls of the vagina was as far as possible scraped down.

The abridged record of treatment is as follows: Two ice-bags were kept continuously applied to the abdomen until the fourteenth day after the operation, to which may be fairly attributed the localising of the peritonitis; ice and brandy, followed by Brand's essence of beef (jelly), were given by the mouth; nutrient enemata were administered continuously every four hours for seven days; a quarter of a grain of opium was given in pill every three hours until the seventeenth day; the four Wells's forceps applied to restrain the hæmorrhage were gently slipped off thirty-six hours after the operation; no secondary bleeding ensued; the vagina was assiduously syringed out with warm carbolic (1 in 40) lotion three times a day, and at each dressing the parts were plugged around the glass drainage-tube with some eight iodoform wool tampons, at the same time the parts were freely dusted with iodoform; the drainage-tube was removed on the tenth day. The bowels were first moved with some difficulty by giving compound rhubarb pills and two castor-oil enemata on the evening of the thirteenth day. This caused the only rise of temperature (100·2°) that took place after the first five days from the operation. The temperature on the day after the operation rose to 101·4° at noon, falling on the third day to 99°, and varied from 100° to 98·6° until the sixth day, when it dropped to normal, at which it remained, except when the aperient enema was given which caused

the sudden rise to 100·2°, to as suddenly drop to normal. The catheter was removed altogether on the morning of the sixth day, when the urine was drawn off until the fourteenth day. For some little time she experienced vesical irritation, but this passed away. Her legs, which were kept well bent by having two pillows tied behind the knees, were allowed down on the fourteenth day; now considered gradually convalescing. The patient was allowed up on the twenty-fifth day after the operation. She ate well; all stimulants discontinued since the fifteenth day She looked well. On examining the parts the vagina was found quite healthy and smooth; no indication of any growth; the finger passed into a cul-de-sac, where a transverse slit was felt, being the position of the os, with no special contraction of parts; no pain; no discharge; little bladder irritation, only after micturition; bowels regular; appetite good; thoroughly convalescent.

Discharged from hospital on Nov. 4th, forty-second day after operation. She was anxious to leave several days before I gave consent, as I wished my colleagues to examine her.

I cannot omit to mention the great skill and attention bestowed on this patient by Mr. Briscoe, our house-surgeon, whose lot it was to have the care of the two vaginal hysterectomy cases operated on by Dr. Wm. A. Duncan, and the second brought to a successful issue; I cannot too highly praise the nurses who were in charge. To my colleagues and to Mr. Jessett I tender my thanks for their kind assistance at the operation.

In the present state of abdominal surgery it is difficult to say what are its limits; but it is one thing to determine what is possible and another what is advisable. To the German surgeons belong whatever credit is due for the modern revival of vaginal hysterectomy; their results were known to be much ahead of those obtained in this country, where they had been bad; their mortality may be put down at 28 to 32 per cent. We may, it is hoped, regard the vaginal extirpation of the cancerous uterus as an eminently rational one in an affection so surely fatal when left to itself as carcinoma, claiming for it no more nor less than what is to be expected from excision of the tongue or rectum, or amputation of the breast. Abdominal hysterectomy is a very fatal procedure; its mortality has been 68 per cent. (Hegar and Kaltenbach), and the death-rate does not appear to be diminishing by increased experience; vaginal hysterectomy, on the other hand, yields more promising results, and is progressively improving in its death-rate, and should be persevered in with the hope that it will ultimately become a far more successful measure than it has proved to be up to the present date.

As no closure of the peritoneum was undertaken in my case, we must presume that a limiting membrane is thrown out by the plastic peritonitis excited by the operation. The bladder falling back on to the posterior wall of the vagina and rectum closes in the depending aperture formed by the removal of the uterus and its right ovary, which was cystic, and its Fallopian tube. In the case of cancer of the cervix uteri the frequency of the disease makes the question of treatment one of ever-persistent importance; the disease is manifestly localised, and not general in many cases, and a hope of cure is not to be denied. Practice seems to have separated itself into two widely divergent lines. On the one hand, to treat the disease by extirpation of the whole organ, or by the supravaginal excision; and, on the other hand, to remove the disease only in those cases in which a protuberant mass presents itself namely, the partial operation on the cervix, with the addition of the application of chloride of zinc, potassa fusa, bromine, or the actual cautery. This latter practice implies the abandonment of "some" women whom a more hopeful view might have helped to cure, and very many of whom might have been relieved, not reckoning of course the immediate risks of the operation. Herein lie the vital importance and necessity of seeing and operating upon cases in their initial stages, if women are to be relieved from misery and suffering and death. Of the final results of the vaginal operation our information is scanty and requires a more rigid following up of each case. Freedom from recurrence may be placed at an average of fourteen months. The prognosis will no doubt improve, especially if the operation be performed early and radically; even if a recurrence take place, the patient suffers little towards the end of her life comparatively, for the disease generally does not recur on the cicatrix in the vaginal fornix. It spreads upwards on to the pelvic cellular tissue, and the patient is saved from hæmorrhage and ulceration.

N.B.—The specimen was shown on Wednesday evening, 14th inst., at the Obstetrical Society of London.

Manchester-square, W.

NOTE ON THE

ACTION OF PARALDEHYDE, THE NEW HYPNOTIC.

BY S. A. K. STRAHAN, M.D.,
ASSISTANT MEDICAL OFFICER, COUNTY ASYLUM, NORTHAMPTON.

PARALDEHYDE, which was first used as a therapeutic agent by Dr. Cervello, of Palermo, some eighteen months ago, has not received in this country the attention it deserves. As a sleep-producer it stands in the same rank with chloral; while in anything like moderate doses it approaches in safety that safest of all sedatives, bromide of potassium. I have employed it over 150 times in about twenty-five cases, and have found but two patients who did not respond to medium doses of the drug. One of these was suffering from acute mania, and the other from severe facial neuralgia. I have given it in mania, acute and chronic, melancholia, dementia, the various stages of general paralysis, during those periods of restlessness and sleeplessness so often met with in idiots and imbeciles, and in simple insomnia, and have found it almost invariably a certain somniferent. Paraldehyde acts more quickly than chloral. When a dose is taken a feeling of warmth, a kind of grateful glow, is experienced, and the patient is often asleep within ten or fifteen minutes. When it does not produce sleep it does not excite, but rather tends to soothe and calm an excited or depressed patient.

The sleep induced by paraldehyde is, I think, a nearer approach to natural sleep than that obtained by the administration of any other drug. It is light, apparently dreamless, and certainly refreshing; the patient can at any time be awakened by a loud word or a gentle shake, and when so aroused does not display any alarm or confusion of ideas, and if left alone at once falls to sleep again. During this sleep the breathing is somewhat slower and deeper than in the waking hours, while the pulse becomes slightly less rapid, and possibly stronger. The temperature (surface) is not changed, the flow of urine is increased, and the skin is not affected. No headache or other unpleasant symptom is experienced on waking, and the appetite is not injured even by the daily exhibition of the drug for considerable periods—in one of my cases for over three weeks.

The dose is from thirty to ninety minims, but more than sixty drops is seldom required to induce sleep; and this, or even a smaller dose repeated within an hour, is much more effective than a single large dose. The paraldehyde is best given as its first adminstrators recommend—that is, with a bitter tincture in sweetened water. It has a pungent taste, but a drachm when combined with fifteen drops of tincture of orange and an ounce or more of water sweetened with syrup makes a not unpleasant draught, never in my experience causing nausea or vomiting. The drug is given off principally or wholly by the lungs, and may easily be detected in the breath for ten, twelve, or more hours.

To sum up now all that can be said in favour of this drug. It is an equally sure hypnotic with chloral, it does not in any case produce excitement before sleep, it leaves no headache nor other unpleasant symptom on awaking, and it does not affect the appetite. These are all matters of not slight importance, but there is one advantage which this drug possesses over chloral which at once gives it a place among our most useful hypnotics, and that is the absence of any depressing or paralysing action on the heart. This absence of action upon the cardiac centre permits of its being given with perfect safety to general paralytics and others to whom chloral would only be given with the greatest caution and with constant anxiety as to the result of even small doses. The new drug may not take the place of chloral in everyday prescribing, but it must supplant it in those, unhappily numerous, cases in which the action of the sedative upon the heart is to be feared and yet where sleep is often so much to be desired.

Paraldehyde may yet be found to be possessed of other

useful properties. I have given it in a few cases of facial neuralgia. In two cases it acted like a charm, while in all the others its effect was *nil*. I have also found it useful in a case of "nervous headache."

Nulla autem est alia pro certo noscendi via, nisi quamplurimas at morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.* lib. iv. Proœmium.

KING'S COLLEGE HOSPITAL.

SIMPLE DEPRESSED FRACTURE OF SKULL; TREPHINING; RECOVERY.

(Under the care of Mr. WILLIAM ROSE.)

FOR the following notes we are indebted to Mr. Penny, house-surgeon. (This case was brought under the notice of the Fellows of the Medical Society, Jan. 26th, 1885.)

H. C——, aged thirty-three, was brought to the hospital at 12.15 A.M. on Nov. 25th, having fallen down a flight of stone stairs. He was insensible; respiration stertorous; pulse very feeble; pupils equally dilated and reacting to light; he had passed urine and fæces in his trousers; there was no evidence of his being in liquor. There was a depressed fracture of the skull, which could clearly be felt, although the scalp was not wounded, one inch and a quarter to the left of the median line, and close to the left occipito-parietal suture. When put to bed, he lay perfectly motionless for about three-quarters of an hour, after which he began to moan and move his limbs slightly, commencing with his arms, his right leg being the last to move. There was no bleeding from the ears, nose, or mouth. A large hæmatoma rapidly developed under the scalp at the seat of injury. He was seen at 1.30 A.M. by Mr. William Rose, who decided to cut down upon the fracture, the patient being still unconscious, and the history of the accident and the abruptly defined nature of the fracture pointing probably to splintering of the inner table. The patient was placed under chloroform in the theatre, and under the carbolic spray an incision about two and a half inches long was made over the most depressed part, and another at right angles, to give additional room to work the trephine, which was then applied close to the edge of the sound bone. The pericranium was carefully detached and turned aside. There appeared to be one long fissured fracture running antero-posteriorly, with two others radiating off at right angles, comprising between them the portion of depressed bone, which, as far as could be ascertained, might have measured a square inch. The diameter of the trephine used was three-quarters of an inch. On removing the semicircular portion of bone, the elevator was inserted, and the bone, which was depressed about the thickness of the skull, was elevated. Two small spicula of the inner table were found loose and removed. As far as could be seen, the dura mater was intact. The wound was then carefully examined for other loose fragments, and none being found, the bleeding points were secured by catgut ligature, the wound united with carbolised silk sutures, a small drainage-tube inserted through the thickness of the scalp only, and dressed with protective and carbolised gauze. The patient vomited freely during the operation, and afterwards became very restless. An ice-bag was applied to the head outside the dressing, and hot-water bottles to the feet. At 3.50 A.M., however, he was sleeping quietly. Respiration 20; pulse 96; temperature 99°; feet warm. At 10.30 A.M. he could be roused to answer questions, but occasionally gave wrong answers. He kept fairly quiet if not touched, but objected to be moved, especially to having a catheter passed; twenty-four ounces of urine were drawn off. 2.30 P.M.: Complained of frontal headache; no pain at back of head; wound dressed; a good deal of bloody discharge; wound looks well. Temperature 99°; pulse 120. Five grains of calomel were ordered. 6 P.M.: Gave so much trouble, and excited himself so much when urine was drawn off, that chloroform was administered for the purpose.

Nov. 26th.—Very restless at night; says the pain is not at back, but in the front of head. Takes about forty ounces of fluid in twenty-four hours. Evening temperature 99·4°; pulse 108. Ordered five grains of calomel and fifteen grains of powdered jalap. He is much more sensible and intelligent, though he sometimes attempts to pull off his dressings and gives wrong answers to questions.

27th.—Bowels opened freely, and passed urine for the first time since the operation. Expresses himself as much better and in less pain. Wound dressed; very slight discharge; drainage-tube left out. In the evening complained of pain over the right parietal bone; very thirsty, and has taken five pints of fluid in twenty-four hours. Still restless if disturbed.

28th.—Slept well; not so restless, and is quite sensible; answers questions well. In the evening the pain over the right parietal bone was worse. Three pints and a half of fluid taken in twenty-four hours. Temperature 98·2°; pulse 68. Ordered five grains of calomel and fifteen grains of powdered jalap.

29th.—Very restless, with severe pain all over back of the head; cannot bear the least noise, movement, or bright light. Pupils still equal and react to light. Isolated and room darkened.

30th.—Wound dressed; healed, except track of drainage-tube. Stitches removed. Ordered two grains of calomel every six hours. Much easier after dressing. Temperature 97·2°; pulse 68. Feels hungry. Allowed a little toast and tea.

Dec. 2nd.—Wound dressed; still a small speck not healed. Can hear very well with both ears. Has rather a vague idea of time (in a darkened room). Can remember nothing about the accident. Temperature 98·2°; pulse 70.

4th.—Slept well. Much more cheerful and pain in the head almost gone. Noise irritates him much less. Allowed a little fish, which he enjoyed.

5th.—Noise does not irritate him. No pain in head. Asked to see a newspaper.

6th.—Taken back to general ward. Enjoys the company.

11th.—Wound quite healed. Some tenderness over scar.

13th.—Allowed to read, which causes no headache. No tenderness. Wishes to go home.

15th.—Discharged on the twentieth day from admission. Total number of dressings, six.

HOSPITAL FOR WOMEN, NOTTINGHAM.

CASES UNDER THE CARE OF DR. GEORGE ELDER.

THE first and second are cases of obstruction of the lower bowel, in the one case by syphilitic stricture, in the other by pressure around the rectum, diminishing its calibre. Both patients did well after the operation of colotomy, and each enjoys a prospect of a greatly prolonged life. In the third case Dr. Elder successfully removed part of the scapula for sarcomatous tumour growing from the bone. The operation, as is usual, was protracted, and there was considerable hæmorrhage. Two months later there was no evidence of recurrence.

CASE 1.—*Syphilitic Stricture and Ulceration of the Rectum; Colotomy; Recovery.*—Mrs. R——, aged fifty years, was admitted into hospital on July 10th, 1883. In addition to a history of syphilis acquired some years ago and neglected, there were evidences of it in the legs in the shape of the remains of rupial ulcerations and tibial nodes. No trouble in defecating was noticed till three years before admission, and this has increasingly become worse; until now the habitual use of aperients is required; but on account of the pain it entails, the patient dreads a movement of the bowels. Of late there has been an almost constant tenesmus and oozing of liquid fæces and muco-pus, and the excrement is formless. As a consequence of the exhausting nature of the discharges, the pain and the interference with nutrition, patient's general health has become very much impaired. On examination it was found that in addition to some degree of ulceration there existed a tight cicatricial contraction of the lumen of the bowel an inch above the anus. Left colotomy (loin) was performed on July 11th. There was no difficulty about the operation, but the progress towards recovery was retarded, first, by suppuration in the track of two of the sutures (carbolised silk); secondly, by formation of pus amongst the connective tissue at the sides of the bowel. Yet, notwithstanding these drawbacks, the patient went out on August 3rd much relieved and benefited by the operation. For some months she appeared amongst the out-patients, seemingly in perfect

health, rid of her former pains and complaining only of the discomfort which an artificial anus entails.

CASE 2. *Extra-peritoneal Hæmatocele; Rectal Constriction; Colotomy; Recovery.*—Mrs. R——, aged twenty-four years, was admitted into hospital on June 5th, 1884. The history of the case runs shortly as follows. Married three years and a half; her health, which had previously been very good, began to decline six months afterwards. There was no evidence of hereditary taint or of acquired syphilis, but her weight from nearly 10 st. had been reduced to between 5 st. and 6 st. when she first came under notice; in fact, she was merely a bony framework covered with skin, and with strength hardly sufficient to get about. It was not until almost directly after the instrumental delivery of her only child at term (which survived but thirteen hours) in July, 1883, that trouble was felt in having a proper evacuation. The motions became suddenly like those of a child, and have remained so since. There is no clear history of acute pelvic inflammation at this or any other time. For a fortnight after delivery she kept her bed, then, after sitting up for a day or two, she had a "stoppage," which compelled her again to lay up for two weeks longer. Since then, with the exception of entire rest being necessitated by another similar attack, she has got about as well as it was possible for a woman to do who was rapidly losing flesh and strength and plagued by the non-control of liquid fæces. At different times she has had, and mostly of late, rather profuse discharges of matter and blood; but there is nothing to show that any collection of pus has ever been discharged by the bowel. There never has been much pain, but the digestive functions have suffered considerably. Up till six weeks since the menstrual function had been normal. On examination under ether there was felt reaching from a short distance within the anus a long, cone-like stricture, of which the upper margin could just be touched by the tip of the finger. The mucous membrane was unbroken. Per vaginam there was discovered a firm, lobulated tumour, bulging into and implicating the recto-vaginal connective tissue. On the anterior aspect of this swelling the uterus was fixed, and it was traced up to the left iliac fossa. On June 7th colotomy in the left loin was performed. An interrupted recovery took place, and she was discharged on the 25th of the same month.

Remarks.—In vol. i. of THE LANCET for 1883 I recorded seven cases of colotomy, amongst which only one was unfavourable, and this was solely due to the late period at which consent was given to the operation. Of the two cases now given there is nothing special to mark in the first, unless it be the immediate relief obtained, and the probable prolongation of life secured by the colotomy. With regard to the second, it is instructive from an etiological standpoint. The suddenness of its onset, the absence of a history of any pelvic inflammation, and to some extent the character of the superficies of the tumefaction, point to a hæmatoma in the connective tissue of the left broad ligament and contiguous parts, as the probable causes of the intestinal obstruction. The use of forceps makes the probability also greater. Some years ago I saw a case of rectal stricture complicated by recto-uterine fistula, produced by parametritis, following an abortion. In this case colotomy was declined.

CASE 3. *Sarcoma of the Scapula; Excision of the Tumour and portion of Bone involved in the Growth; Recovery with a useful Arm.*—Mrs. B——, aged twenty-three years, was admitted on Sept. 27th, 1882. Her mother died at thirty-seven years, of "internal tumours," but in other respects the family history was good. Her own health had been fair until twelve months before, when she noticed a small growth in the posterior part of the left axilla. This continued to grow rapidly and caused great pain, especially down the inner side of the arm. So intense had the pain become on movement that she had for some time prior to admission ceased to use the left arm. Although she said her general health had not failed, yet she had an unhealthy appearance, which might in some measure be due to her confinement seven weeks before. The tumour occupied the greater part of the infra-spinous space, and was evidently firmly attached to the bone. It somewhat encroached upon the ventral surface. The integument covering it was healthy. The tumour was smooth-surfaced and not particularly tender. On Oct. 1st Dr. Elder made a T-shaped incision over the body of bone, and found, on reflecting the flaps, that by excising it from just beneath the spinous process the tumour with its connexions would be embraced. A considerable quantity of blood was lost in doing this, and time. After all hæmorrhage had been arrested and the parts brought together, a boro-glyceride dressing was applied. The wound was rather slow in healing, doubtless due to her enfeebled condition, and when she returned to her home in the country on Nov. 4th part of it still required dressing. In the summer of 1883, at the local meeting of the British Medical Association, she was shown to the members, possessed of a very useful arm; in fact, seemingly not much the worse for her loss. Dr. Truman examined the tumour microscopically, and found it held together by a slender framework of connective tissue. (*a*) Round cells, with one large or two smaller nuclei; (*b*) unipolar nucleated cells; (*c*) free nuclei, and (*d*) large pigmented cells at regular and frequent intervals.

SHEFFIELD GENERAL INFIRMARY.

CONGENITAL MALFORMATION OF THE LARGE INTESTINE; LITTRÉ'S OPERATION; AUTOPSY; REMARKS.

(Under the care of Mr. CHAS. ATKIN, F.R.C.S., House-Surgeon.)

CONGENITAL absence of the large intestine is very rare, and we would draw attention to the interesting case recorded by Mr. Atkin. Operations in cases of malformation of the large bowel usually afford only temporary relief, the malformation being one amongst other evidences of immaturity, and the cause of the symptoms of obstruction being overlooked until the child is exhausted by vomiting, pain, rupture of the intestine, or the onset of peritonitis. Nevertheless, it is necessary to do what is possible, and the operation selected by Mr. Atkin—Littré's operation in the left loin—is that generally selected by the surgeon when it is not possible to relieve the patient by perineal incision.

A male infant, two days old, was brought to the infirmary not having passed any motion since its birth. On examination, a small depression was found at the usual situation of the anus, but it would not admit even a small probe. The abdomen was distended, hot, and redder than normal. In Mr. Favell's absence from town, Mr. Atkin explored the ischio-rectal region, but failed to meet with any bowel, so an oblique incision was made above and parallel to Poupart's ligament on the left side. Not finding the colon, a piece of small intestine which presented itself at the wound was stitched and opened in the usual manner. Meconium and flatus came freely from the wound. The child was evidently eased and took some milk with a few drops of brandy without vomiting; after a quiet night, during which the temperature was never elevated, it began to sink, and died during the evening of the following day.

At the autopsy the whole colon and rectum were found to be rudimentary, being about the diameter of an ordinary quill; at first sight the tube seemed to be a solid cord, and it was not till after removal of the whole alimentary canal that it was found that firm meconium could be pressed along with the aid of considerable force. The cæcum and vermiform appendix were differentiated from the main canal, but corresponded in degree of development to it. The narrowest part of the canal was four inches above the cæcum, being only one-sixteenth of an inch in diameter, and admitting only the point of a fine probe. An inch and a half above this was the place where the bowel was opened; the edges were found glued to the abdominal wall by adhesive lymph, with no extravasation into the cavity. There were no other deviations from the normal, no umbilical hernia, and no remains of the vitello-intestinal duct.

Remarks.—Though several instances of imperforation of the small intestine have been recorded with a normal colon and rectum, yet cases of such extensive malformation are surely uncommon. The parts seemed to have remained as they are in the early embryo, when, on the whole, the calibre of the large intestine is less than that of the small, and yet the arrest cannot have been very early, because the formation of the cæcum, which is supposed to take place about the third month, was well advanced. That Littré's incision seems the one by which the bowel is more readily reached is easily seen, and Amussat's operation would certainly have failed in this case, and necessitated a further exploration in the groin. Strange to say, another child was brought in the same evening, aged three days; similar measures were adopted, and it lived and throve for twelve days, then gradually it began to fade, and died at the end of the fortnight. In this case the rectum ended half way down on the back of the bladder, the sigmoid flexure was found to have

been opened, completely emptying the colon above, whilst below the rectum was immensely dilated with indurated meconium, forming a firm mass which filled the false pelvis and compressed the bladder. Probably this, by deranging digestion, caused the death of the child, as the artificial anus was perfect, patent, and without any signs of peritonitis. How to avoid such a condition is very difficult, but no doubt, if suspected, the best plan would be to insinuate a bent probe through the opening down the rectum and endeavour to make a perineal opening; but it would have failed in this case, for two reasons—first, it would have required more force than one would think justifiable to have pushed a probe through such solid material; and, secondly, the bowel ended too high up, quite out of reach. In a third infant with congenital malformation, under the care of Mr. A. Jackson (to whom and Mr. Favell I am indebted for the privilege of publishing these cases), the anus was normal, the imperforation being above; the child was only brought to the infirmary on the fifth day, the deficiency not having been found out till the night before. Such cases more than hint the necessity of examining newly-born infants suffering from constipation with a probe.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Perforation of the Mastoid Cells.—Simultaneous Double Distal Ligature for Innominate Aneurysm.

AN ordinary meeting of this Society was held on Tuesday last, Dr. George Johnson, F.R.S., President, in the chair.

Mr. DALBY read a paper on cases in which Perforation of the Mastoid Cells is necessary. The paper does not include the ordinary cases, where, after inflammation of the middle ear, the usual signs of abscess in the mastoid process with softening of the external plate of bone are present, as they are often met with, especially in children, and treated by a free opening. In some of the cases in this paper the external plate of bone was healthy, and yet there was pus in the mastoid cells. In others, although the external plate of bone was diseased, the matter took a circuitous route under the scalp, at one time into the temporal region, at another into the occipital region and along the muscles of the neck. Although in some cases the indications for perforating the mastoid cells included continuous pain in the mastoid region, œdema on deep and continued pressure, pain increased by the recumbent position, a high temperature and severe rigors, as already detailed in the contribution on "Diseases of the Mastoid Bone" (Transactions, vol. lxii.), cases of pus in the mastoid cells and healthy external plate of bone are now related from which one or more of these symptoms were absent. Although the external osseous plate is found to be healthy, the perforation should still be made if the constitutional symptoms point to the presence of pus within the bone. The operation is performed with a drill, which is provided with a stop to enable the precise depth of the perforation to be determined; thus, all risk of penetrating too deeply is avoided, and the operation is free from danger. Six cases were selected, each of which illustrated some point of importance. In one case the patient was comatose, but afterwards recovered. In two others the inflammatory process was prolonged for many months before the evidence of the presence of pus was conclusive. In another symptoms of infantile paralysis were present, and disappeared after perforation of the cells had given exit to pus. In another the pus not only passed forward under the temporal muscle, but towards the occiput under the splenius capitis and complexus muscles, and down the neck to a level with the thyroid cartilage. In conclusion, the author expresses his belief that perforation of the mastoid cells is more urgently and frequently required than the literature of the subject would lead one to infer.—The PRESIDENT said that he had seen many cases of fatal disease of the brain caused by disease of the internal ear, which might possibly have been prevented by the apparently trivial operation advocated by Mr. Dalby.—Mr. URBAN PRITCHARD said that the commonest cases were those in which the pus was superficial to the mastoid cells. Suppurative disease of the mastoid cells may exist, and not even œdema or any sign, with the exception of tenderness on percussion need be present to indicate the presence of the disease. The operation was a simple one. Wounding of the lateral sinus was possible if care were not taken. In one case he had opened the mastoid cells and found them empty, even though marked symptoms, like unilateral flushings with epileptiform fits, were present; strange to say, the fits and other symptoms subsided after the apparently unsuccessful operation.—Mr. W. HAWARD said that if the records of a hospital were searched, evidence would be found of the frequency with which large numbers of cases are admitted on account of convulsions, coma, delirium, and affections of the pyæmic class, proving rapidly fatal, and due to suppuration of the mastoid cells. It was very important to recognise the symptoms which call for the operation. Some surgeons have urged that a route already exists by which matter can make an exit, but the communication between the tympanum and the mastoid cells was very small, and, as a matter of fact, the pus does not escape in the fashion supposed. The tendency of pus to burrow in many directions was also another reason for surgical interference and the establishment of a direct opening into the mastoid cells.—Mr. HOWARD MARSH, in his experience at the Hospital for Sick Children, could bear testimony to the statements of Mr. Dalby and Mr. Haward. He related two cases in which the patients were insensible, and which made good recoveries after the operation of opening the mastoid cells had been performed. The danger of wounding the venous sinuses was a real one, and he remembered to have had to use great care in trephining for depressed fracture of the skull: in one case the longitudinal sinus, and in another the lateral sinus, had to be carefully avoided.—Mr. DALBY, in reply, said that the mastoid cells did not always communicate sufficiently freely to allow of free drainage when one of their number was fully opened. In America the use of the chisel and hammer had recently been advocated, but this would be an outrageous procedure.

Mr. RICHARD BARWELL read a paper on a case of Simultaneous Double Distal Ligature of the Carotid and Subclavian Arteries for high Innominate Aneurysm. The patient, a female aged forty-eight, was admitted into the Charing-cross Hospital on February 16th, 1884. She was thin, pale, and anæmic. Her health had been uninterruptedly good until eighteen months ago, when she had a fall, without immediate ill effects. A year ago she noticed a sense of throbbing at the upper part of the right side of the chest, and very soon afterwards neurotic pains and loss of power in the right arm. On admission the right half of the sternum, the two upper costal cartilages, with their interspaces, were protruding and pulsatile. In the outer half of the episternal notch, and behind the inner head of the right sterno-mastoid muscle, was a pulsatile tumour, which involved the carotid artery. The voice was very low and toneless. Very little air entered the lungs. The apex beat of the heart was not displaced. The right radial pulse was very small, and ceased altogether four days after admission, when no pulse could be felt throughout the arm nor at the third part of the subclavian artery. During the next twelve days the patient became more feeble, less air entered the chest, and the line of dulness rose higher. On February 28th Mr. Barwell tied the carotid, and as the immediate effect of ligaturing this vessel was an increased pulsation of the sac, he tied the third part of the subclavian also, lest the obstruction should yield and the aneurysm again increase outward. The patient, though weak and disturbed by some intestinal troubles, went on well until March 28th, when recurrence of pulsation in the cervical part of the tumour took place; this continued for seventeen days, when it diminished and soon ceased altogether, and definitive consolidation followed. On May 6th she left the hospital. On June 4th she showed herself at the institution; there was no enlargement at the upper part of the chest nor any tumour to be felt in the neck. Over the site of the late aneurysm the percussion note was clear, and the respiratory murmur was distinct. No pulse could be felt in any branch of the right carotid and subclavian arteries. Mr. Barwell believed the symptoms clearly indicated a high innominate aneurysm involving both the artery and its bifurcation, because pain in the right arm was a very early symptom. It was probable that the disease first began in the subclavian branch, and that the subsequent affection of the inner side of the innominate compressed the subclavian and that portion of the sac arising from the subclavian artery. Anatomical reasons were given for this

view, and attention was directed to the absence of tumour at the clavicular part of the sterno-mastoid muscle. In his remarks the author dwelt upon the spontaneous cessation of the pulse in the right arm, and stated the means he had taken to ascertain whether cerebral injury would follow ligature of the carotid artery in this case. No cerebral symptoms were caused by the deligation, although probably no blood found its way directly to the right side of the brain. He also drew attention to the return of the lungs to the normal state. Questions were propounded as to the mode in which soft clots in aneurysmal sacs were disposed of when recurrence of pulsation occurs. This case was the sixth instance of double distal deligation that Mr. Barwell had brought before the Society. Of these five had been successful, the one narrated to the date of last seeing the patient (August, 1884) perfectly so. He said Mr. Mitchell Banks had brought from Liverpool a specimen of ligature of the innominate artery.—The PRESIDENT inquired as to the causation of the aphonia. He said the loud ringing brassy cough which so frequently accompanied aneurysm of the aorta was almost sufficient for the diagnosis of the disease.—Mr. MITCHELL BANKS had performed the operation of simultaneous double distal ligature on a soldier for innominate aneurysm rising high in the neck. He ligatured both the carotid and subclavian vessels with kangaroo tendon ligatures. The patient did well till the thirteenth day, when there appeared a fulness and swelling, which steadily increased, and was found to be due to extensive effusion of blood. Death followed in about a month, and then it was found that the aneurysm had been nearly occluded by laminated clot. The subclavian artery at the point of ligature was completely destroyed, and this explained the concealed hæmorrhage. The question must still be considered open as to what was the best material for ligaturing the great vessels. Kangaroo tendon, which was first used by Girdlestone, seems to be absorbed too readily; he had not yet used ligatures made from the aorta of the ox. Nearly all the cases of ligature of the large arteries about the region in question died from secondary hæmorrhage, and a most serious question was the material to be used as a ligature.—Mr. TIMOTHY HOLMES said that he had been, and still remains, at issue with Mr. Barwell as to the best method of treatment. He believed that the best method was not simultaneous ligature of the carotid and subclavian arteries, but ligature of the carotid artery alone, and, if necessary, subsequent ligature of the subclavian artery. The most successful case on record was the old one of Evans, performed in 1828, in which the patient lived for nearly forty years after the ligature of the carotid artery, and then died from some unknown cause. This case was strikingly like that described by Mr. Barwell. Occasionally a similar result followed ligature of the left carotid for aneurysm lower down; in one such case of aneurysm of the transverse part of the arch of the aorta in a young woman an excellent result followed. The first case reported in Mr. Bellamy's pamphlet had undergone very definite improvement after the application of the ligature to the carotid artery, and the reason for the subsequent ligature of the subclavian artery in this case was not evident. The lives of these patients were precarious, and it was important to recognise that ligature of the subclavian added greatly to the risk of a fatal result. Where the stress of the aneurysm fell chiefly on the subclavian part of the sac, it might be proper to deligate that vessel first, but as a rule ligature of the carotid artery produced more effect, for it gave off no such considerable branches as does the subclavian in the first two parts of the course. Ligature of the carotid artery completely arrested the current of blood. He considered the ox-aorta ligature a very much better ligature than catgut prepared in any way; the kangaroo tendon also formed an admirable ligature, and the failures with it were probably owing to not pulling the ligatures sufficiently tight.—Mr. HOWARD MARSH congratulated Mr. Barwell on the success of his remarkable group of cases. He thought the discussion of the treatment of aortic and of innominate aneurysms ought to be kept apart. In Mr. Barwell's present case it should be borne in mind that the pulsation of the subclavian artery had ceased before the ligature was applied to that vessel. He considered that closure of the carotid and subclavian arteries at the same time was really not often effected; in another alleged case, for instance, the carotid was all but occluded at the time of the operation. It should be remembered that rapid dilatation of the arch of the aorta followed ligature of the subclavian artery. He agreed with most of Mr. Holmes' remarks on the value of ligature of the carotid alone. In one case Mr. Barwell had ligatured the carotid so loosely that the lumen of the vessel was still patent, and the first and second parts of the subclavian were still open. Reference was made to one of Mr. Heath's cases in which the aneurysm affected the ascending part of the arch of the aorta, and which was greatly benefited by distal ligature of the carotid artery. He considered that the way in which these operations take effect in different cases was not sufficiently recognised. With regard to the kangaroo ligature, he had reason to be satisfied with it on the whole, though in the hands of Mr. Willett and of himself the ligature had broken on more than one occasion. In the sixty-sixth volume of the Royal Medical and Chirurgical Transactions an account of a case operated on by him is recorded.—Mr. SPENCER WATSON had used kangaroo tendon and ox-aorta ligatures, and did not think it necessary to cut through the inner and middle coats of the artery, but merely to bring the sides into apposition.—Mr. BARWELL, in reply, reviewed the cases which Mr. Banks and Mr. Heath had recorded. The weakly state of the patients would rather make one perform the double ligature at one operation than expose the patient to the risks of a second operation later on. Were it not for the danger of the operation, he would rather ligature the first part of the artery, in order to cut off as much blood as possible from the aneurysm.

CLINICAL SOCIETY OF LONDON.

Hemianæsthesia from Congenital Brain Disease.—Scrofulous Gland Disease with Phthisis.—Stricture of the Œsophagus and a new Method of using the Œsophageal Catheter.

AN ordinary meeting of this Society was held on January 23rd, Mr. Arthur E. Durham, F.R.C.S., Vice-President, in the chair.

Dr. ALTHAUS read the particulars of a case of Hemianæsthesia from Congenital Brain Disease. The patient was a girl aged eleven, who was admitted into the hospital for epileptiform seizures, and what had been called paralysis of the left side. There was no inherited neurotic tendency, but she had been delivered with instruments. On examining the side which had been believed to be paralysed, Dr. Althaus found that there was no paralysis of motion anywhere, but complete hemianæsthesia from the vertex down to the toes. Sensibility was unduly keen on the right side, and the line of demarcation between the sensitive and anæsthetic zone was sharply defined. In order to show that she felt nothing in the left hand, the patient herself bit and scratched it, ran a pin right into the flesh of the hand and forearm, and said she had never felt anything there as long as she could remember. All the various forms of sensation—viz., of contact, pain, temperature, and pressure—were completely lost; and the anæsthesia affected likewise the mucous membranes of the eyes, nose, and mouth. The superficial reflexes were lost, while the deep or tendon reflexes could be elicited. The left pupil was insensible to the influence of light. There was also hemianæsthesia of all the nerves of special sense; ophthalmoscopic examination of the fundus of the eye showed the optic disc to be of a pearly white lustre, and the calibre of vessels small. The patient was blind, deaf, and deprived of smell and taste on the left side. There was also ischæmia, as punctures did not bleed. Some ataxy of movement existed in the left hand. Dr. Althaus diagnosed hæmorrhage in the posterior third of the posterior segment of the white internal capsule in the right hemisphere, affecting only the paths of sensation, but not the pyramidal strands which conduct the power of motion, and are situated more anteriorly in the capsule. He thought the hæmorrhage to be due to delayed birth and instrumental delivery. It would be an absurdity to assume the existence of hysterical hemianæsthesia in a newly born infant, nor could the idea of a tumour be entertained, as the degree of the affection had never varied throughout life. The hemianæsthesia in this case yielded completely to a single application of electricity, by the proceeding known as faradisation of the skin; and Dr. Althaus explained this surprisingly rapid result by assuming that the clot of blood, which was the primary cause of the affection, had been absorbed soon after birth, but had left a condition of functional paralysis in the part originally affected. The suitable stimulus of electricity then overcame the impediment which

had so long existed in the conduction of sensitive impressions to those cortical centres by which they are appreciated.—Dr. ANGEL MONEY inquired as to the causation of the atrophy of the left optic nerve which apparently existed. In all the cases of congenital brain disease on which he had made an autopsy the lesion was chiefly situate in the cerebral cortex. He also pointed out that epileptic seizures were present in Dr. Althaus's case.—Dr. DAVID B. LEES asked what the evidence was that the condition dated from birth.—Dr. ADENEY asked whether the condition of the optic nerve after the restoration of sight and other senses had been observed.—Dr. ALTHAUS, in reply, said that there was not actual atrophy of the optic nerve, but as much change as might be accounted for by disuse. There had been no re-examination after recovery, as the patient left the hospital suddenly. The father had always noticed a difference between the state of the two sides of the body. It was possible that the epileptic seizures were due to "some squeezing" of the cortex, though he did not think the hemianæsthesia was due to lesion of the cortical substance.

Mr. FREDERICK TREVES read a paper on a case of Scrofulous Gland Disease with Phthisis. A female patient, aged seventeen, presented a number of scrofulous glands in the neck and axillæ. These swellings had appeared two years previously, and were advancing in spite of all treatment. The lungs were sound. The more prominent glands were evacuated by means of thermo-cautery and scraping, and may be considered to have been cured. In six months the remaining glands were treated in the same way and did well. Two months after the second operation the patient was attacked with pleurisy, internal evidences of phthisis appeared, and the patient died six months after the last surgical procedure. The case raises the very important questions as to how far surgical interference is justifiable in scrofulous gland disease, and to what extent such interference may be conducive to phthisis. In spite of the issue in the present case, Mr. Treves argued in favour of operation in properly selected cases. The cases must be carefully chosen. In many instances judicious operations have entirely cured cases that had resisted treatment for years. He quoted the statistics of the hospital at Beck-sur-Mer, where all scrofulous gland affections are treated by surgical means, and where the results have been most encouraging. Mr. Treves, in conclusion, reviewed the various operative measures adopted in the treatment of these cases.—Dr. BURNEY YEO inquired whether the bacillus of tubercle had been discovered in the contents of the scrofulous glands which Mr. Treves had removed. In the discussion in France surgeons were at variance on the nature of the morbid process in scrofulous glands.—Mr. R. J. GODLEE did not feel sure that scrofulous diseases were so very uncommon in connexion with phthisis. During the past few weeks he had seen at the Brompton Hospital two cases of hip-joint disease, three cases of spinal caries, one of sacro-iliac disease, several cases of fistula, one of caries of the sternum, another of disease of the shoulder-joint, and many cases of scrofulous testicle. With regard to the treatment, he considered that blistering was a useful method for subduing strumous glands if the original source of irritation have been removed. If the diseased glands were not firmly adherent he would advise removal with the knife. If the glands were firmly adherent, the method of scraping out the cheesy matter with the sharp spoon would be best. He confessed that he did not see what advantage there was in using the thermo-cautery.—Dr. J. GREY GLOVER inquired whether Mr. Godlee had seen strumous testicle without any disease of the chest. This was answered in the affirmative.—Mr. CHARTERS J. SYMONDS said that at the discussion on the subject of removal of scrofulous joints in cases of phthisis it was allowed that the patients generally improved after removal of the arthritic mischief; so that he considered it would be valuable to remove strumous glands even if the patient had slight affection of the lungs.—Dr. EWART was not sure that scraping the glands was a process at all analogous to the proceedings of nature. In ordinary disorganisation of the glands the lymphatics were closed by a natural pathological process, whereas by scraping paths by which infection could take place might be left open. Removal of the entire gland seemed to him to be the best method of treatment; for if a small portion be left, multiplication of any of the micro-organisms present might take place with possible evil consequences.—Mr. S. PAGET related the following case, which illustrated the process of nature in subduing disease. The patient, when first seen, had scrofulous disease of the right epididymis, with some affection of the apex of the right lung. He went away to the seaside, and returned with the whole of the body of the testicle involved and fungating; later on the whole of this mass sloughed entirely away into the bed, where it was found one morning. At a future date the left epididymis became affected, and he was again sent to the seaside. On his return the phthisis had not advanced, but the body of the left testicle was affected, and with discharging sinuses. There was nothing in the anatomical arrangement of the lymphatics which could account for the supervention of disease in the left testicle when the right was affected. Mr. BARWELL said that the distinction between strumous glands and tubercular glands ought to be borne in mind. He should have thought, in opposition to Mr. Treves, that if the knife were not available when the disease was so extensive, neither would the thermo-cautery be able to reach the furthest limits of the disease. Leaving the capsule of the gland after scraping had not commended itself to him as a good method of treatment.—Mr. TREVES said that in his opinion all strumous glands were tubercular. There were several stages or degrees of tubercular affections of the glands. The first might be spoken of as a low form of chronic inflammation; in the second stage large cells, which Rindfleisch had regarded as special, and giant cells were to be seen; later still the primitive tubercle of Küster and others made its appearance; and, finally, we may meet with pertectly typical miliary tubercle in strumous glands. In many cases no proper bacilli were found. But he considered that in all such glands the process involved was the same; no doubt there might be a relation, difficult to interpret, between the inflammatory process and tubercular disease. He had employed the statistics of the Scrofula Hospital to determine the frequency with which strumous affections were associated with phthisis. He had seen a great deal of harm come of using local irritation, as by iodine, for the treatment of strumous glands. It was under the influence of irritation that glands enlarged in the first instance, and further irritation would increase the mischief. In cases of enlarged glands at the nape of the neck counter-irritation might be useful; but where the application of an irritant did good, the lymphatics going from the irritated part did not go to the affected gland. He had used the cautery to puncture the skin, and would employ it in all cases, for it prevented that undermining of the skin which gave rise to the thin purple integument which was so difficult to heal. The risk of opening the gland was very much diminished when the thermo-cautery was used, and this treatment left a carbonised tunnel leading into the gland, and thereby prevented undermining of the tissues. Moreover, no drainage-tube would be required; and in his experience there was much less scarring than after the use of the knife. In cases of joint disease the patient was confined to bed, and the suffering from pain and suppuration was out of all proportion to that which accompanied a strumous gland. He thought Dr. Ewart's suggestion a valuable one, and yet in those instances where the glands had exceedingly thick capsules the spoon might be freely used without much danger of opening up paths for infection. He had been misunderstood by Mr. Barwell, for he certainly would not attack a gland unless the whole disease could be removed. There were degrees of surgical procedure, the most severe being excision, then came scraping, and last, the thermo-cautery. In his hands scraping had proved very effective, and Mr. Teale of Leeds had had similar success. Any kind of treatment would be useless unless the neck were kept at rest.

Mr. CHARTERS J. SYMONDS read an account of a case of Malignant Stricture of the Œsophagus to illustrate the use of a new form of permanent œsophageal catheter. The patient, a man aged forty, who was exhibited wearing one of the tubes, gave a history of seven weeks' dysphagia before coming under treatment on June 23rd, 1884. At that time he was unable to swallow, and it was impossible to pass a bougie. He, however, on the day of admission managed to swallow some milk, and in a few days took fluids freely. The first tube was passed on July 15th. This was the usual long œsophageal catheter, and projected from the mouth. It proved a source of great irritation, and had to be removed in thirty-six hours. The long tube induced much laryngeal irritation, and by plugging the stricture prevented the descent of the saliva, and gave rise to constant expectoration. The tube brought before the Society by Mr. Symonds was designed to remove these inconveniences while retaining the advantages of the method

of treating œsophageal stricture by permanently wearing a tube. The gum-elastic tube is about six inches long; one end expands into a funnel having an outside diameter of one-half to three-quarters of an inch; the other has the same construction as an ordinary catheter. The tube is passed through the stricture, the funnel resting on its upper face, thus preventing the further descent of the tube. For removing it a piece of strong silk is attached, carried out of the mouth, looped over, and fastened behind the ear. The patient had worn the catheter since July 15th. It has been changed at various intervals—at first of a week, and later on of a fortnight and three weeks. No difficulty was experienced in removing the tube, nor did the patient suffer any inconvenience from its presence. The man can swallow fluids freely, and has gained in weight. The advantages claimed for this form of tube are that, while maintaining a passage into the stomach, it does not interfere with deglutition, produces no irritation, is not unsightly, and, moreover, retains to the patient the pleasures of taste. The man is able to move about with comfort, and, except for the silk passing out of his mouth, is not aware of the presence of the tube. It was suggested that if the cases of this disease were taken earlier a large tube might be employed, and the patients kept in comparative comfort, while at the same time the number of cases necessitating gastrostomy would be greatly diminished. It was the desire to avoid this operation, often so unsatisfactory, that led to the construction of the tube. (These tubes are made by Messrs. Down, of St. Thomas's-street, S.E.)—Mr. DURHAM considered that the instruments were of great value, though whether they would be applicable for strictures just below the larynx, would have to be determined by future experience. — Mr. BERRY asked what was the smallest size of catheter employed. If tubes having a terminal aperture at each end were used, they might be passed over the catgut guide, which could be got through the tightest stricture. He had employed, and would recommend the use of, a soft flexible tube, which, however, could not be passed alone unless the stricture were a very slight one. The flexible tube had the advantage that it could be used for some time without causing any irritation of the larynx. An account of the three cases to which he referred would be found in the St. Bartholomew's Hospital Reports for 1884.—Mr. SYMONDS, in reply, said that the largest catheter he had used was No. 10, English. His tube might be adapted for strictures as high as the level of the cricoid cartilage.

The following living specimens were shown:—Dr. W. B. Hadden: Choreiform Movements, probably dating from birth, in a female child aged twelve. Mr. Ballance and Dr. Hadden: A case of Enlargement of Hands and Feet, with Œdema of the Face.

MEDICAL SOCIETY OF LONDON.

Trephining for Depressed Fracture.—Statistics of Cancer of the Tongue.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, President, in the chair.

Mr. W. ROSE read a paper on a case of Trephining for Depressed Fracture, which is fully detailed in the "Mirror of Hospital Practice," p. 202.—The PRESIDENT congratulated Mr. Rose on so successful an operation.

Mr. F. BOWREMAN JESSETT read a paper on Cancer of the Tongue, with especial reference to the frequency with which the disease attacks this organ, its etiology and treatment. Of 2227 cases seen at the Cancer Hospital, the tongue was the seat of the disease in 190 cases, or about 8·5 per cent. Statistics collected by Sir James Paget, Mr. Sibley, von Winiwarter, and Mr. Barker were given and compared, and there was a general agreement in the results arrived at. Mr. Barker's statistics showed a higher percentage of cases of cancer of the tongue (16·3 per cent.), and this high rate might have been due to the large number of Welsh miners admitted to the University College Hospital. There was no organ in the body which is subjected to such rough treatment as the tongue, and this fact, combined with the surroundings of the organ, affords some explanation of the frequency with which cancer occurs in the tongue. Phthisis, syphilis, and hereditary tendencies were classed as the constitutional causes of cancer of the tongue. He believed that tubercular ulcers were disposed to become cancerous. He thought no one would deny the difficulty that frequently existed in diagnosing between tubercular, syphilitic, and cancerous ulcers of the tongue. He strongly advised excision of the tongue if treatment for a fortnight effected no benefit. With regard to the relation of cancer with ichthyosis, Mr. Morris had so thoroughly worked out this point that he should not treat further of it. Age had considerable influence on the development of the disease. The average age in the statistics he had collected was fifty-two, the youngest patient was thirty-two, and the oldest seventy-nine. Treatment was next considered, and as the disease was regarded as not purely local, he believed that some day a remedy for cancer would be found. Early removal of the nodule was strongly insisted upon, and the incisions should go wide of the disease. Division of the gustatory nerve and ligature of the lingual artery were of value in extreme cases. The various operations which had been practised for removal of the tongue, or a portion of it, were briefly reviewed. The operation for removal of the whole tongue was at least two hundred years old. Mr. Barker had found that in only 17 out of 170 cases had the patient been free from disease at the end of a year; in 639 cases operated on the death-rate was 20·7 per cent. An examination of all the published cases which were available had led him to the conclusion that no one operation yielded the best result in all cases. The death-rate after operations with the écraseur was 8·5 per cent., whereas that after the operation by scissors was 31 per cent. The écraseur was most suitable when the anterior part of the tongue was the seat of the disease, and the knife or scissors was the best when the diseased area was small. The difficulty of removing the whole of the growth when large by the écraseur was referred to, and a preference for the operation by ligature of the lingual artery and removal with the scissors was expressed. On the whole, however, the statistics spoke strongly in favour of operation with the écraseur. Dr. PURCELL said that he had operated on six cases with one death. The electric light in his hands had not proved very successful, as the light went out at the critical moment in the fatal case. He believed that a preliminary ligature of the lingual arteries was absolutely necessary.—Mr. FREDERICK TREVES thought that more might be said in favour of Billroth's operation of removal with the scissors preceded by deligation of the lingual arteries. The difference between the effects of the écraseur and the scissors was the contrast between a lacerated and an incised wound, and the contused state left after the action of the écraseur was necessarily followed by some sloughing. Salivation probably had a good deal to do with the foulness of the discharge from the mouth; he therefore recommended the excision of a short portion of the gustatory nerve. With the necessary precautions, he thought that Billroth's operation was the one which could be carried out with scientific deliberation and care. He could not agree with Mr. Whitehead's practice of not ligaturing the lingual arteries.—Dr. H. SNOW thought that the galvanic écraseur gave the best results; and secondary hæmorrhage was very rare after its occurrence.—Mr. BARWELL looked upon the scissors as a form of écraseur. It was very difficult to get at the whole of the diseased tissues when they were situate far back. He then described the operation which he had devised, and which allowed of the removal of the tongue as far back as the base of the epiglottis. The wound is made just above the hyoid bone, and through this opening the wire used in cutting is introduced.—Mr. WALSHAM asked whether, in his experience, Mr. Jessett had ever known a tuberculous ulcer become cancerous. Tuberculous ulcers are rare, and he had seen but six cases in eighteen years. He looked upon the écraseur as the most favourable method of removing the tongue.—Mr. WALTER PYE asked whether we were on the same ground when different speakers spoke of the wire and the galvanic écraseur. Scissors, properly used, were cutting instruments, and left clean cut surfaces.—Mr. JESSETT briefly replied, and considered that the wire was preferable to the galvanic écraseur.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, Jan. 14th, Dr. Henry Gervis, President, in the chair.

The following specimens were shown:—Dr. Edis: Uterus removed by Vagina on account of Cancer. Dr. A. Routh: Phosphatic Calculus removed by Urethra. Dr. Heywood Smith: Electrical Speculum. Dr. Handfield Jones, jun.: Fibroid Uterus removed by Porro's Operation. Dr. Purcell:

Cancerous Uterus removed by Vagina. Dr. Godson: Cancerous Cervix removed by Operation, and Microscopical Sections.

Dr. W. A. DUNCAN read a paper on the Extirpation of the Uterus. The author, having had two cases of vaginal extirpation, proposes to give details of them, and then to discuss the whole subject of extirpation in its various aspects. Case 1: The patient, aged thirty-seven, married, one child eleven years old, was admitted to the Royal Hospital for Women and Children on Dec. 11th, 1883, with a slight attack of pelvic cellulitis. When seen a few days previously, there was found a small growth of epithelioma on the portio vaginalis near the os uteri, and only involving the anterior tip of the cervix. The attack of cellulitis passed away gradually, and on Jan. 22nd, 1884, extirpation was performed per vaginam according to Schroeder's method; great difficulty was experienced in ligating the broad ligaments, which were shortened from the inflammatory thickening left; the double drainage-tube was inserted, and iodoform plugs in the vagina. The patient made an uninterrupted recovery, and was discharged cured on the thirty-ninth day, with an arched cicatrix in the vagina, but no induration whatever. She was readmitted on June 14th (five months after operation) with cough, pain over the lower ribs on the right side, night sweats, and pyrexia. On the 25th an indurated mass was felt on vaginal examination above its roof; pelvic glands enlarged. The patient continued in much the same state, with intermitting pyrexia, the temperature remaining, as a rule, between 100° and 105°; she was discharged, at her own request, on July 16th, and died at home on November 1st. Case 2: Mrs. P——, aged fifty-four, admitted on Feb. 4th, 1884, with ulcerating epithelium of cervix. Married thirty-two years, eight children. Quite well from menopause (ten years ago) until eight months before admission, when hæmorrhage followed coitus. Vaginal extirpation on Feb. 26th, as in Case 1. Collapse set in as soon as the peritoneal cavity was opened, and death took place twelve hours after operation. The author having discussed the advantages and disadvantages of the abdominal and vaginal methods, gave statistics of all the cases he could find, showing that after 137 abdominal extirpations there were 38 recoveries and 99 deaths, being a death-rate of 72 per cent.; whilst after 276 vaginal extirpations there were 197 recoveries and 79 deaths, being a death-rate of 28·6 per cent. The details of the after-treatment were then discussed, the author being of opinion that there was no necessity either to sew up the wound in the vagina, to put in a drainage-tube, or to plug the vagina; but he insisted on the importance of the free use of iodoform locally, of the upright posture for the first ten days, and of the free administration of opium. He next reviewed the various malignant and non-malignant diseases for which the operation has been done, and was of opinion that in none of the latter was it ever justifiable; that in sarcoma and carcinoma of the body of the womb and mucous membrane of the cervical canal it was indicated; whereas in cancer of the portio vaginalis, for which it has frequently been performed, the death-rate is four times greater than after supra-vaginal amputation of the cervix, and the ultimate results are almost precisely alike (32 per cent. being free from recurrence [two years later). Hence in these cases he argues that we are not justified in performing it.—The PRESIDENT expressed the thanks of the Society to Dr. Duncan for his paper, and for his kindness in having tables of the cases quoted printed for the use of Fellows. He indicated as lines for discussion personal experiences of the operation and the pathology of the disease as bearing on the justifiability of the operation.— Dr. BRAXTON HICKS offered a word of caution in regard to accepting the evidence of the curette in cases occurring in the child-bearing period of life, since the mucous membrane of the uterus under the influence of pregnancy and other stimulants presents an appearance much like that of malignant disease. Again, sarcomatous polypi, which may return, and ultimately cease, cannot be distinguished by the microscope from truly malignant growths—Dr. JOHN WILLIAMS thought our knowledge of the operation was sufficient to enable us to form a judgment, at least as regards the vaginal and abdominal methods. The abdominal method is far the more fatal (72 per cent.), and is as likely to be followed by recurrence as the other; it has therefore practically been discarded. After the vaginal method the mortality is from 25 to 34 per cent.; the author estimated it at 28 per cent., which is a little above the mortality of ovariotomy for many years after it had become a recognised operation, and this mortality might be considerably reduced. But the two operations are very different. If the patient recovers from ovariotomy, she is restored to health and strength, and so remains. After extirpation of the uterus for cancer, however, the disease recurs in a large number of cases within six months, while very few remain free after two years, and only one has remained free for five years. Again, most of these cases are those of cancer of the cervix, and not of the body, and supra-vaginal amputation gives better results than extirpation. This clearly limits the operation to cancer of the body. The diagnosis of this, however, presents difficulties. Dr. Williams has done the operation four times, and the only patient who recovered from it died a month later of fæcal fistula high up in the small intestine. The patient had been examined under ether, and the uterus was found freely movable, very slightly enlarged, and no growth could be discovered in the pelvis, nor any adhesions between the uterus and surrounding organs; but at the operation a soft adhesion was found between the fundus and a coil of intestine. The disease had passed through the uterine wall to the small intestine, and three or four days after the operation liquid fæces passed by the vagina. Here the most careful examination failed to discover the extension of the disease beyond the uterus. Again, before a just opinion of extirpation can be formed the course and history of cancer of the body must be better known. This disease is far commoner than was formerly supposed, and its course is longer than was believed. In the early stages of cancer the pain is not severe, but becomes so after the disease has invaded the deeper tissues. Now, when recurrence takes place after operation the disease is placed at an enormous advantage; it recurs at the edge of the cicatrix, and at once attacks the deeper tissues, being associated with the severe suffering of an advanced stage of cancer. This means that after the operation the patient has a few weeks or months of comfort and supposed freedom from disease; and then the disease returns and occupies the position it would have occupied, after months of comparatively little suffering, had it followed its course unmolested, for the tissues through which it would have had to make its way had been removed by the surgeon's knife.—Mr. THORNTON expressed his agreement with the conclusions of Dr. W. Duncan, and also with the remarks of Dr. Williams. He was not an opponent of operations for cancer; in the case of the breast it is possible to remove the whole disease and all suspicious glands. The surroundings of the uterus, however, were very favourable for the spread of cancer beyond the possibility of complete removal. He thought the attack of cellulitis in Dr. Duncan's case was very likely due to displacement of cancerous elements during examination, and might account for the rapid recurrence after an apparently successful operation. Here he must express his dissent from the author; he believed the practice of curetting cancer of the uterus to be very dangerous and apt to spread the disease. He had thought that the one possible indication for the operation was severe pain, but after Dr. Williams's remarks he was inclined to alter his opinion. Cancer of the body is slow in growth, and he thought it was rarely painful as long as it was confined to the body. The fetor of the discharge might be controlled by insufflation of iodoform. In cancer of the cervix extirpation was inferior to amputation of the cervix and the application of chloride of zinc. He preferred this method to all others on account of the power which chloride of zinc appeared to possess of following up the cancer elements and destroying them. Dr. W. Duncan had omitted one point—namely, the necessarily imperfect removal of the tube by the vaginal method. As they are part of the uterus, any operation which leaves them behind must be imperfect. This condemns the vaginal method as completely as the frightful mortality of the abdominal method condemns that operation.—Mr. DORAN believed that there were anatomical reasons against the extirpation of the cancerous uterus. Mierzewsky and Lebec had shown that in the connective tissue between the body of the uterus and the peritoneum there is a dense network of lymphatics, whilst two wider lymphatic plexuses form a collar round the uterine and vaginal portions of the cervix. The lowest of these communicates freely with the vaginal lymphatics. All these networks form and empty themselves into two or three large trunks running to the obturator gland, passing along the lower border of the broad ligament. He had felt this gland soon enlarged in cases of cancer of the cervix,

though not with the stony hardness like that of cancerous axillary glands, except in advanced cases, where the uterus was already fixed and deeply ulcerated. This disposition of the lymphatics favoured the spread of cancerous elements, and the whole of the broad ligaments could not be removed.—Dr. PLAYFAIR agreed with the conclusions expressed in the paper. In the most common form of cancer in which extirpation was most likely to be of value the diagnosis was uncertain till it was too late to operate. Apart from epithelioma, cancer of the cervix was always obscure till fixation occurred, which distinguished it from hyperplasia, &c. The progress of the disease is sometimes surprisingly rapid. In one case seen with Mr. Thornton one week sufficed to fix a perfectly mobile uterus and to veto the operation. Even in cancer of the body alone he was doubtful if extirpation is justifiable. He then related a case in which he had suggested extirpation three years ago, and the patient is still alive in comparative comfort, the bleeding having been controlled by insufflation of iodoform and tannin. In epithelioma of the cervix, removal of the diseased tissue and the application of chloride of zinc is the best procedure. He related a case in which the patient remained in comparative comfort four years after this operation, though the disease had recurred. He related a case in which, though the case was well adapted for extirpation, he had advised Sims's operation. The patient went to Sir Spencer Wells, who had, at her request, extirpated her uterus. The disease recurred within a year, and she died. He had no doubt Sir Spencer Wells would acknowledge, in the light of recent experience, that if the patient had been let alone or Sims's operation done, her expectancy of life would have been as good, to say nothing of the risks of the operation.

On the motion of Sir SPENCER WELLS the discussion was adjourned to the next ordinary meeting in March.

ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Surgical Section was held on Dec. 12th, the President, Dr. Bennett, in the chair.

Mr. THOMSON read a paper on three cases of Ovariotomy which had all been successful. They were performed in the presence of visitors and the students of the hospital, as were all the cases operated on by his colleagues. Listerian precautions were used; the pedicle in each case was ligatured and dropped into the pelvis, and no drainage was considered necessary. The author discussed the opinion expressed by Mr. Lawson Tait that "no surgeon engaged in constant attendance on the promiscuous cases admitted to a general hospital should perform such an operation as ovariotomy," and maintained the right of the general surgeon to operate in abdominal cases. He held that such an opinion was an absurdity, as it really meant that no surgeon should amputate a limb, the wound being more likely to suffer from infection than the peritoneum. An uncomplicated case of ovariotomy he regarded as one of the easiest operations in surgery. Dr. ATTHILL said the intra-uterine disposal of the pedicle was that almost universally adopted. Success depended on careful attention to details, by which, whether the operation was performed by a specialist like himself or by a general surgeon like Mr. Thomson, the result would be as good as was obtained in London or elsewhere. The first question of importance was as to the size of the tumour before commencing to operate. As the result of his experience, success was greater with a small than with a large tumour, and therefore he advocated early operative treatment. Another point of importance was the size of the incision; Mr. Lawson Tait advocated an exceedingly small incision. Sir Spencer Wells and others, one of fair size. Having operated fifty times himself, he was decidedly in favour of a fairly large incision, but not larger than was absolutely essential to ascertain if anything were wrong. He objected to new sponges as being hard to free from sand, and on that account he used the same set of sponges, twelve in number, again and again, first boiling them in 1 in 1000 solution of corrosive sublimate, and keeping them in carbolic lotion. In a certain proportion of cases drainage was an advantage, and if used carefully there would be no bad result. While in favour of antiseptic precautions, he objected to the use of the spray as producing cold in the abdomen.—Dr. FRAZER recommended liquid sulphuric acid for the purification of sponges.—Mr. H. G. CROLY advocated ovariotomy by the general surgeon as one of the most simple operations in the whole range of surgery, and one, too, that ought to be performed not only in the presence of visitors but of students, as he did not approve of letting students fancy there was some mystery in it.—Dr. STOKES concurred with Mr. Thomson in the justifiability of the general surgeon undertaking ovariotomy. Of his last eight cases six consecutive ones were successful. In all his cases he had made a free incision and used the spray, but he took the precaution of warming the carbolic solution. In the unsuccessful cases he employed drainage; but in the successful he laid it aside, and he believed the time was not far distant when drainage would be given up, not only in ovariotomy, but in most other surgical operations. Let precautions be taken, as Esmarch indicated, by securing every bleeding vessel and by sufficient pressure to render the wound dry; let what had been happily termed "the toilet of the peritoneum" be properly carried out, and drainage would become unnecessary. In his own cases what was called uterine epistaxis had been a source of anxiety. He asked whether or not that form of hæmorrhage occurred in Mr. Thomson's cases, and his opinion as to the desirability of checking it.—Dr. BARTON said Sir Spencer Wells informed him that he used the Listerian method of dressing, which, while he could not say it made much difference in the result, made a very great difference in his own feeling of confidence. He did not allow the spray to play on the open peritoneum, as harm was sometimes done by reducing the temperature.—Dr. ROBERT MCDONNELL said Sir Spencer Wells informed him that there was no fever accompanying the operation when he used antiseptic precautions, and therefore he adhered to the antiseptic method.—Dr. NEVILLE argued that specialists had the advantage of knowing better than the general surgeon how to treat contingencies, apart from the question of diagnosis. Epistaxis was common, and in his opinion did not much affect the result.—Mr. KENDAL FRANKS said though the development of ovariotomy was due to specialists, that was no argument why the general surgeon should not perform it. No hard-and-fast rule could be made as to drainage.—Dr. HENRY showed that where there was a large amount of broken-down adhesions the drainage-tube was useful, it being impossible to tell how much the abdomen would take up.—Mr. THOMSON, in reply, was glad Dr. Atthill concurred with him in the desirability of removing small tumours as soon as diagnosed. Abdominal section was practically without risk. It was most important that the sponges should be clean, and hence he used new ones, which he had put through a solution of hydrochloric acid for twenty-four hours to get rid of the particles of sand, and threshed and steeped again in water. In his cases he used the spray, but in the last he did not bring it directly over the wound. Epistaxis occurred in the last case, but as the patient had menstruated a week before the operation, he regarded the epistaxis as an irregular return of it, and in three days it passed off in the usual way. He testified to the success which attended Mr. Stokes' cases under the same circumstances noticed in his paper. He was in favour of the operation being performed in the presence of students as well as of visitors, but he preferred its being done in the ward rather than in the theatre, to prevent risk of contamination. While he did not say drainage should be done away with, it ought to be diminished, the presence of the tube itself giving rise to irritation and consequent effusion into the peritoneal cavity, which would countervail the advantages.

CAMBRIDGE MEDICAL SOCIETY.

AT a meeting of this Society, held on December 5th, 1884, Mr. J. Carter, F.R.C.S., President, in the chair,

Mr. BALDING (Royston) exhibited a specimen of Dislocation of Hip, with dissection of part, which he said was interesting as showing the parts involved in a simple dislocation of the hip, death having taken place from other causes forty-eight hours after reduction. It was removed by Dr. Archer from a boy thirteen years of age, who was admitted to the Royston Hospital on October 3rd, 1884, having been, as he said, just thrown from a cart by the horse running away. The patient was unable to walk in consequence of some injury about the right hip, and as he lay in bed the leg appeared much shortened and the right thigh lay across the lower part of that of the opposite side, there was marked prominence in the right gluteal region,

and it was thought that the head of the bone could be felt on the dorsum of the ilium; any attempt to move the limb produced intense pain in the hip and thigh. Under the influence of chloroform reduction was soon effected by manipulation. The effects of the chloroform soon passed off, notwithstanding the unfavourable head symptoms, but signs of compression with complete insensibility and convulsions gradually supervened, and death occurred on October 5th. At the post-mortem examination a fracture was found extending through the base of the skull, and effusion of blood within the cranium sufficient to account for death.—Dr. ANNINGSON had examined the specimen, and found much extravasated blood beneath the glutei muscles and amongst the nerves and vessels, which rendered dissection difficult. The gemellus inferior was torn from its attachment to the tuber ischii; the obturator internus and quadratus femoris were lacerated, and the obturator externus was much bruised near its attachment to the ilium. On cutting through the quadratus a valvular rent in the back and under part of the capsular ligament about an inch and a quarter long was found. The round ligament was torn through obliquely, the tear commencing close to the head of the femur.

Mr. WHERRY showed a patient suffering from Myopia caused by an orbital growth. He was first seen in July last with a right eyeball protruding and rotated outwards. On deep pressure in the upper orbit a fulness can be felt at the upper and inner aspect. The history was of double vision and of pain in the right temporal region during more than two years. He used to suffer also from severe attacks of pain in the body and limbs like "neuralgia all over" and sometimes "sciatica." He was troubled with habitual constipation and bleeding piles. The pain in the head increased so much that he was driven by sleeplessness to seek advice at the hospital. He never had any venereal attack; is fifty-three years old; has been married twenty-four years. Wife alive, aged forty-two; has had fifteen children, five are living, ten dead; of these, three died young of phthisis, two died in infancy, and five consecutively were still-born. There is no error of refraction of the left eye, which is moderately presbyopic, S=$\frac{2}{24}$. In the right protruded eye S=$\frac{2}{60}$, with 3 D., S=$\frac{2}{24}$ nearly. There is a rather blurred margin to the nerve entrance in this eye, as if from optic neuritis; and it presents a marked contrast to the other nerve entrance, which is clear and definite. He has a crossed diplopia; the image belonging to the left eye is higher up and tilted. On Dec. 5th, after the application of a 4 per cent. solution of muriate of cocaine, a puncture was made into the orbital swelling with a large grooved needle, and nothing came away but a little blood; the patient stated that he suffered very little pain from the operation. The treatment has been the internal use of iodide of potassium and perchloride of mercury; and although there is no apparent change in the deformity during the past four months, yet there has been no pain whatever, and the sight of the eye has also improved; but the most interesting point in the case appears to be the myopia, which seems to have been produced by the pressure, perhaps both extra-ocular and intra-ocular, though there has never been any tension.

Mr. DEIGHTON read notes of a case of Adenoid Growths of the Naso-Pharynx. C. L——, aged five years and a half, a delicate-looking little girl, born in the West Indies, of English parents, came to England three years ago, where she had measles very badly, and suffered from a profuse purulent discharge from her nose, but did not have any ear complications; since then she has suffered more or less from stuffiness of the nose, which has increased of late, until now she is quite unable to blow her nose, always sleeps with the mouth open, snores, and even in the day-time continually has her mouth open and breathes noisily. Of late she has been getting somewhat deaf. On examination of the anterior nares the mucous membrane of the inferior turbinated bones was not hypertrophied or unnatural in colour. The tonsils were only slightly enlarged. Rhinoscopy was impracticable, but on examining the vault of the pharynx a large mass of post-nasal growths, which bled very readily, was detected by the finger. These were removed by Lowenberg's forceps. In order to re-establish respiration through the nose, the mother was told to check the child whenever she was seen to be breathing with the mouth open, and a chin rest with tapes to tie over the head was ordered to be worn during sleep. This treatment was entirely successful.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

AT the meeting on December 4th, Mr. W. A. Garrard, President, in the chair,

Mr. S. SNELL introduced (by card) two female patients, one with Exophthalmic Goitre (monocular), and the other with Congenital Palsy of the Third Nerve.

Mr. WRENCH exhibited twelve Pure Cultivations of Bacilli prepared by Mr. Watson Cheyne, F.R.C.S., Director of the Biological Laboratory, International Health Exhibition, and described the mode of cultivation and the proof that a given organism is the cause of a disease.

Mr. SIMEON SNELL demonstrated the effects, on a youth, of Cocaine as a Local Anæsthetic when dropped into the eye. Mr. Snell referred to a number of operations in which he had made use of it. These included, among others, two cataract extractions, two cases of needling for opaque capsule, three squints, tarsal cysts, pterygrium, including several others, and cases also of removal of foreign bodies from the cornea; two iridectomies, one being for glaucoma. He believed the drug to be of great service, and it would in many instances obviate the necessity for chloroform or ether. The mydriatic effects were mentioned, and its use in aural surgery—for example, polypi—as well as in general surgery was alluded to. Mr. C. Atkin, Mr. Pye Smith, and Dr. Hannan made observations.

Mr. ARTHUR JACKSON exhibited a Cystic Sarcoma of the Tibia. The whole thickness of the tibia in its lower third was eaten away, only a thickened membrane being left in front. The patient, a man, had been knocked on the shin nineteen months previously. He had been under treatment twelve months ago, and suffered severe pain, especially at night. Later on he was under hydropathic treatment, and he had always been a vegetarian. On September 5th last he was admitted into the infirmary, and on the 6th the limb was amputated at the lower third of the thigh. Mr. Jackson referred to vegetarian diet as not being good for reparative processes; the stump was going to the bad until the patient consented to take some meat.

Mr. ATKIN read the notes of a case of Congenital Coccygeal Tumour, occurring in the practice of Mr. Arthur Jackson at the infirmary. It sprang from the right side of the sacrum and coccyx, the bone being on the left deficient. Double talipes equino-varus was also present. Microscopical sections were shown of the growth, when it was seen to be of a very mixed character; fatty, fibrous, and cartilaginous elements were seen, as were well-marked ducts lined with columnar-shaped epithelium. Cysts were also present, interspersed amongst the fibrous tissue, containing a semi-opaque yellowish granular material. Mr. Atkin made remarks on the different descriptions that have been given as to the pathology of these tumours, and laid stress on the total absence of anything that might be considered sarcomatous.

Mr. LONGBOTTOM showed a specimen of Stricture of the Pylorus. The patient, a man aged sixty-five, had only complained of indisposition for two months before death, then he suffered from dyspeptic symptoms, and vomited large quantities of sour fluid containing sarcinæ, which resisted all treatment. At the post-mortem the stomach was found enormously distended and attached to many surrounding organs, including the spleen, a hard rounded mass occupying the pylorus; the growth was well defined, not extending to the duodenum; the other organs were healthy. Mr. Longbottom remarked on the question of operation in such cases.

Mr. LONGBOTTOM also showed a Scirrhous Enlargement of the Left Lobe of the Liver from a man aged fifty-one. He had complained of pain in the right side for twelve months. An enlargement, the size of a hen's egg, was noticed three months ago; it did not occasion much pain. When seen seven weeks before death a considerable nodular swelling occupied much of the abdomen. At the post-mortem examination the left lobe of the liver was found enormously enlarged, extending to four inches beyond the ensiform appendix on the left side, attached to the diaphragm and abdominal walls in front; the growth weighed ten pounds and a half.

Dr. CLEAVER read a paper on Infantile Diarrhœa; and after rapidly reviewing the different forms of diarrhœa and the treatment to be adopted, and pointing out the danger of medical men attempting to treat diseases of

diarrhœa alike without sufficiently inquiring into the cause and origin of each case, he proceeded at greater length to review the form known as summer diarrhœa. After considerable experience at the Children's Hospital and in private practice he had come to the conclusion that this particular form of diarrhœa was, in a great measure, due to temperature and feeding, and particularly was this the case if cow's milk had been the means of nourishing the child. He invariably changed the diet to Swiss condensed milk, and with the happiest results, never having had occasion to regret in a single instance the substitution of Swiss milk for cow's milk.—In the subsequent discussion the following gentlemen took part: the President, Dr. Dyson, Mr. Reckless, Dr. Lyth, and Mr. Jackson.—Dr. Cleaver replied.

Reviews and Notices of Books.

The Origin of Cultivated Plants. By A. DE CANDOLLE. London: Kegan Paul and Co. 1884.—This little volume is a valuable contribution to the knowledge of the subject, being the embodiment of the most painstaking antiquarian and scholarly research, and the result of scientific acumen applied to the misleading statements of writers in times when botany had not yet developed into a science. It is one of a number of valuable works forming an international scientific series, and the world-wide reputation of its author is sufficient guarantee of the position which the book will occupy in botanical literature. The original work was published in French in 1882, and was an amplification of a chapter on the subject in the author's work on Geographical Botany published in 1855. Every effort has evidently been made by the author to keep pace with the rapid increase of information derived, during recent years, from the exploration of ancient tombs, and with the reports published concerning the cultivation of species recently introduced into plantations, and in general the efforts have been crowned with complete success. How difficult this is to attain is shown by the fact that coca leaves are not mentioned as being cultivated in India and Ceylon, although the shrub has been grown there within the last year or two, whence the London market will doubtless be supplied before long; as well as by the fact that the tree yielding cassia bark is spoken of as an uncultivated species, whereas Mr. C. Ford published about a year ago the fact that it is regularly cultivated in China. It is also somewhat disappointing to find nothing about the history of the cultivation of cinchona. Indeed, there is evidence that the work might be considerably extended in relation to plants that have been brought under cultivation within the last century, and of others which, like the kola nut, are now growing in other countries, where they have been carried by negro slaves in years gone by. Two hundred and forty-nine cultivated plants are, however, treated of, and all, except the lentil and chick-pea, are traced back to their origin, these two having apparently become extinct in the wild state; while wheat, maize, the broad bean, and safflower seem to be in course of extinction as wild plants. Several medicinal plants formerly, or even now cultivated, are included in the number above mentioned; and some interesting facts may be gleaned from their history; thus, the castor-oil plant is stated to derive its name from having been confounded by the Spaniards and Portuguese in Jamaica with the "agno casto" (*Vitex Agnus-castus*), the word "casto" being altered by the English traders into "castor." In a future edition, which will doubtless be soon required, the word "carthamine" might be advantageously replaced by the English name, "safflower;" and in the statement that the leaves of the *Ilex paraguayensis* contains a principle "analogous" to that of tea, the word "identical" would more correctly represent the fact. Nevertheless, it is a work which should find a place in the library of every botanist, and is indispensable to every student of economic botany.

The New Chemistry. By JOSIAH PARSONS COOKE, LL.D., Erving Professor of Chemistry and Mineralogy in Harvard University. Eighth Edition, Remodelled and Enlarged. International Scientific Series. London: Kegan Paul, Trench, and Co.—The eighth edition of a book on pure chemistry, even although remodelled and enlarged, calls for little remark. The fifteen lectures reproduced in its pages are excellent examples of popular science, by no means frivolous, requiring, indeed, careful study, and yet intelligible to the untrained student. Thermo-chemistry, the practical value of which is daily growing, is fairly well noticed, but the important discrepancies of Berthelot and Thomsen in this field of discovery are passed over, no doubt for want of space. We observe with regret that, after all that has been published on the subject, the periodic law is ascribed to Mendeljeff instead of to Newlands, who was its actual discoverer. However, so well-written and lucid a book deserves its popularity.

The Asclepiad, No. 5, Vol. II.—The January number of this journal contains four chief articles, dealing with widely different subjects, and afford an excellent illustration of the versatility of Dr. Richardson's literary powers. There is also an important contribution, which is well illustrated, entitled "Further Researches on Euthanasia for the Lower Creation." The biographical and critical essay on Benjamin Rush—the American Sydenham, as Isaac Lettsom styled him—is certainly interesting, and the portrait which illustrates it is on the same high scale as those which have heretofore adorned the *Asclepiad*. The Opuscula Practica, which form a standing order in this quarterly, are sure to be welcomed as "mites in science," containing useful practical notes. A few points in the properties of ethyl and methyl bromides, and methyl iodide are given in the current number.

Health Lectures for the People. Delivered in Manchester, 1882-3-4. Sixth and Seventh Series, pp. 143 and 148. Manchester: Heywood. 1884.—The sixth series of lectures appears to be a reprint of those published in 1882, which were noticed in THE LANCET at the time of publication. The seventh series consists of the lectures on what the committee under whose auspices they were delivered call "Sanitary Biology." They may be described as a course of popular lectures on physiology. We have considerable doubts whether they are well adapted for the classes for whom instruction is intended on the subject of promoting and maintaining their health as individuals and that of their families; but from this we must except the lecture by Mr. Brooke on washing and bathing, and that by Dr. Simpson on sleep and rest. The remarks in the latter upon the injurious effect of home lessons at night for next day's school are especially deserving of consideration.

A Dictionary of Medicine, including General Pathology, General Therapeutics, Hygiene, and the Diseases peculiar to Women and Children. By Various Writers. Edited by RICHARD QUAIN, M.D., F.R.S. New Issue in Six Monthly Divisions. Price 5s. each. Division I. London: Longmans, Green, and Co. 1885.—This Dictionary of Medicine is so well known that it is only needful to notice the fact of its issue in parts. It will, no doubt, be a convenience to many practitioners to take in the work in this form and subsequently bind it. There are no alterations in the text or general style of the work; it is simply a reissue in parts.

Reports of the Meetings of the Scientific Association, recently held in Montreal and Philadelphia, as given in "Science," Aug. 29th to Oct. 3rd, 1884. Published by the Science Company, Cambridge, Mass.—This journal, which has now reached the close of the fourth year of its issue, resembles the English journal *Nature* in the number, variety, and interest of the communications which appear in its columns. The numbers forwarded to us contain full

accounts of the various addresses and proceedings in sections of the meeting of the Scientific Association that met in America in the summer and autumn of the present year. Many of them are well worthy of careful perusal and consideration.

Official Year-book of the Scientific and Learned Societies of Great Britain and Ireland. London: Charles Griffin and Co. 1884.—This work, prepared to meet a want long felt by scientific workers generally of a representative book containing an account of the many scientific bodies engaged in active work throughout the kingdom, is compiled from official sources. The aims and objects of each Society are given, with the number of members, and the conditions under which its work is prosecuted. The first issue now offered to the public consists of fifteen divisions, fourteen of which relate to British societies, and contain an account of over 500 which are actually engaged in original research; while in the fifteenth is given a list of over 1400 scientific bodies prosecuting inquiry throughout the world. The volume will prove useful to those for whom it is intended, and we are glad to learn that it is intended to publish it annually.

A Dictionary of National Biography. Edited by LESLIE STEPHEN. London: Smith, Elder, & Co. 1885.—We have received the first volume of this work, which concludes with an account of Queen Anne. The notices given of each individual are full and clear, and, as far as we are able to ascertain, accurate. The work, when complete, will form a valuable addition to the library of every student of the past

CANTOR LECTURES.

By G. V. POORE, M.D., F.R.C.P.

ON CLIMATE IN ITS RELATION TO HEALTH.

AT the third lecture on Monday, Dr. Poore began by stating that the number of microbes found by Miquel in the air, varying from zero on the Alps to 28,000 per cubic metre in hospital wards, seemed to show that the number was proportionate to density of population, for density of population meant an aggregation of productive foci of microbes. The breath of even healthy persons often contained microbes, and the moisture in the breath, if collected, was putrescible, and when condensed upon the walls of an apartment or elsewhere, doubtless formed productive foci for micro-organisms. In hospital wards, which were occupied for twenty-four hours, and were never empty for months together, and in which productive foci were furnished by diseased lungs, diseased bodies, wounds, and collections of expectorated and other excreta, and where the temperature was high and uniform, it was no wonder that the microbes in the air became excessive. It was important to bear in mind the fact that productive foci might exist outside the body, and that all collections of putrescible matter were possible sources of danger. The indictments against sewers and cesspools, which were both productive foci, and often contained specific poisons, were too numerous to require more than an allusion. They were often direct causes of disease, and they acted most powerfully in an indirect manner by encouraging overcrowding, and the building of houses with no outlet except into the sewer. This is a most important consideration, because overcrowding probably took the first place among causes of high mortality.

Attention was next directed to some diseases which were certainly caused by floating matter in the air; and in the first place Blackley's interesting experiments were dealt with, whereby he demonstrated that his own sufferings from "hay fever" were distinctly caused by the pollen in the air. That fungoid spores in the air might work incalculable mischief was illustrated by reference to the potato disease, and the strong evidence which there was to show that when the disease first broke out in this country in 1844 the spores of the Peronospora Infestans were air-borne and travelled from Belgium to the Isle of Wight, and thence by the Midlands to Scotland, infecting the whole of the potatoes in the country in the course of a few days.

In suddenness of onset and extent of the area invaded epidemic influenza could not but remind us of the potato disease. That influenza was caused by an aerial poison all the facts of the epidemics seemed to show; and Sir Thomas Watson, writing in 1837, regards rather with favour than otherwise the idea that the disease might be due to multiplying organisms of a vegetable or animal nature carried hither and thither by the atmosphere. There is certainly more to be said in favour of such a theory now; and when the next epidemic of influenza occurs, Miquel and other workers in the same line may possibly settle the question.

Phthisis had lately been moved from the class of local maladies and classed with infective diseases; and the influence of the bacillus tuberculosis, which had been discovered by Koch, was now very generally accepted. Many of the facts which we have all along recognised with regard to phthisis seem strongly to support the idea of its being an infective disease. Among these facts may be mentioned the following:

1. The tendency of a local deposit of tubercle to infect the whole body and run an acute course which is sometimes strikingly like that of other infective disorders.

2. The true infectiveness of phthisis is difficult to prove: (*a*) because the onset is usually very insidious; and (*b*) because the disease is so extremely common that it is always impossible to exclude infection in any case. The fact that overcrowding is of all causes the most potent in determining phthisis is a strong argument that it is often caught by inhaling infective matter in overcrowded and ill-ventilated rooms and workshops.

3. The fact that the disease, once started, is very prone to progress in spite of removal of the cause is very suggestive of an infective process, as against the traumatic action of chemical or mechanical impurities in the air. The undoubted heredity of phthisis should be no stumbling-block to the acceptance of phthisis as an infective disorder. Supposing that the infective particle passed from parent to child in utero, there was nothing strange in that. Again, Raulin's experiment showed how the presence or absence of some minimal ingredient in the cultivating medium might cause an organism to flourish or languish, and what we call a family predisposition might very well mean that the blood and tissues of certain individuals are peculiarly well suited for the growth of the bacillus tuberculosis. Again, the inheritance of a long narrow chest probably involves a feeble coughing power for expelling catarrhal products. These products would be very prone to lodge at the apex, where the lung is without thoracic support, and there form a nidus for the growth of the bacillus.

The commonly accepted facts with regard to phthisis thus seem to be singularly in harmony with the infective theory of its causation. The fact discovered by Dr. George Buchanan that phthisis diminished in a district after effective sewerage had been carried out is as easy to explain on an infective theory as on any other. Sewerage works would remove a certain number of bacilli from the neighbourhood of our homes, and, by drying the sewage-sodden soil and making cesspools unnecessary, would deprive the bacilli of some circumstances favourable, if not for their growth, at least for their vitality. Phthisis does not by any means stand alone as an infective disease which is intensified by filth in the neighbourhood of our dwellings.

Soil as a climatic factor was next considered, and the circumstances which give rise to malaria were discussed. A review of the peculiarities of mountain climates was next entered upon, and it was strongly urged that these health-resorts would soon lose their reputation if the authorities allowed houses to be packed together without sufficient curtilage, and without regard to sanitary considerations, and if phthisical patients were to be crowded into barrack-like hotels to spend about twenty out of the twenty-four hours. Such a proceeding, in view of the infective nature of phthisis, seems to be of all things the most undesirable. Phthisis was in no sense a disease dependent on climate, except in so far as in damp cold climates like our own people were too prone to crowd together in dwellings and to neglect to provide any adequate ventilation.

In conclusion, Dr. Poore stated that he had endeavoured to show that many so-called climatic diseases were in reality diseases due to our own negligence. If the study of hygiene had been productive of good at home, it had no less removed much of the terror which tropical climates formerly inspired. The truth of this was shown in a very striking manner by the returns of sickness and mortality among British troops both at home and abroad, proving how death and disease had steadily diminished as our knowledge of sanitation increased.

THE LANCET.

LONDON: SATURDAY, JANUARY 31, 1885.

IT was hardly to be expected that the debate which has recently occupied three meetings of the Royal Medical and Chirurgical Society should have been limited to the mere question of fact as to the presence of KOCH'S bacillus in phthisical lesions, and the relative preponderance of the bacilli at various stages of the phthisical process. So far as this—the actual subject of the very important paper contributed by Dr. KIDD—was concerned, the opinions of those competent to speak from personal knowledge were in the main concordant with KOCH'S results. It is perhaps rather surprising that no further divergences on such points were forthcoming than those expressed by Sir A. CLARK, Dr. T. ACLAND, and Mr. MACNAMARA; for, as Dr. WILSON FOX suggestively reminded the Society, the detection of this bacillus depends upon its behaviour with certain aniline dyes; and, as Dr. KIDD and others pointed out, it is present often in very minute numbers. In a matter so wholly dependent upon the use of special technical methods, there is greater room for discrepancy than in matters of macroscopical observation; and it seems to us that in such a question as this a negative fact is of less importance than usual, especially when the positive facts are so numerous and harmonious. We may take it, then, as established that in the lesions of the phthisical there are to be found, in varying quantity, the bacilli discovered by KOCH in tubercular products. Here, then, we have valuable aid on a diagnostic point, by seeking for these micro-organisms in the expectoration. This was early illustrated in many quarters after the knowledge of KOCH'S discovery became general; and we may recall the case related by Dr. WHIPHAM at the Medical Society, where a doubtful diagnosis of tuberculosis was rendered more certain (and as it proved correctly so) by the detection of the bacillus in the sputum. It is not often that a resort to this additional aid in diagnosis is called for, since clinically the signs and symptoms of phthisis are characteristic enough. There is, however, one class of cases in which it may be serviceable—viz., where signs of consolidation persist at a lung apex, following an acute attack diagnosed as pneumonia. The knowledge that the process, although it may be arrested, that has gone on in that lung is of the same essential nature as that which in another subject may spread and destroy, would put the physician on the guard for further manifestations of the diathesis so revealed. Here we are confronted with the questions raised by Dr. GREEN, which touch the gist of the whole matter: Do we know any apex consolidations which are not tubercular; and, if they do not soften, what test of their tubercular character have we? Or may they, at first simple, become tubercular? And if the bacillus is not detected in such cases, is it justifiable to assume that they are not tubercular? Replies to these questions are not forthcoming with our present knowledge. All we can surmise is, in the absence of the organisms, that such cases are either to be placed in the category of arrested tubercle or that it is possible for a simple inflammatory or pneumonic change in the lung which remains unresolved to become a nidus for the bacillus. Speculation may beat in vain around such questions as these; we do not possess the key to their solution, and must trust to the accumulation of well-considered facts to bear us to the right solution. The valuable addition made by Dr. FOWLER from his experiences in the post-mortem room was helpful as showing how frequently phthisical lesions remain arrested. "What proof is there that these obsolete semi-cretified fibroid masses are the relics of a local tuberculosis?" ask the sceptics. "The proofs derived from analogy," reply the observers; and to this may be added the testimony of M. DÉJERINE, who has detected the bacillus in the softer caseous outer zones of such products, and who has convinced himself of the common tubercular origin of all (or nearly all) the calcified nodules in the lung, which are amongst the most common of any pathological change whatsoever. Both Dr. WILSON FOX and Dr. MOXON pointed out that under certain conditions of the process it was not to be expected that the agent which is assumed to initiate it should still be present; and it does seem to us by far the best way to explain all the facts, clinical as well as pathological, besides having the merit of simplicity, to believe in the arrest of a tuberculous process and the possible immunity from auto-infection owing to the changes that have occurred around the primary local focus. This doctrine harmonises well with the facts, spoken to on all sides, as to the relative prognostic significance of an abundance or paucity of bacilli in the sputa.

How, then, does the acceptance of this doctrine affect the whole question of the nature of phthisis? It implies that it is an affection which cannot be initiated spontaneously, but it by no means disregards the idea that for its origin, and even more for its extension, other factors than the introduction of a poison from without are essential. There must be a vulnerability of the organism, a disposition to undergo the phthisical changes; and not only a general vulnerability such as may be supposed to be derived from inheritance, but often a local vulnerability determining the appearance of the tubercular lesion in this or that region. We fully concur with Dr. GREEN that the discovery of the bacillus in no respect alters the opinion which pathologists had arrived at regarding the infective character of tuberculosis. Ought we now—with KOCH—to admit this morbid condition into the category of contagious disease? On this question the data are strikingly insufficient; for although logically there seems to be no escape from the view that tubercle may be transmitted by inhalation and by food, we are surrounded by a host of other considerations which must first be explained away before that view can be finally accepted. Here, again, the subject of predisposition comes to the front; and if measures of prophylaxis are to be taken at all, it must be in respect to such individuals in whom the predisposition exists. We deprecate as emphatically as does Dr. WILSON FOX even the suggestion of treating the unhappy victims of consumption as if they were dangerous to the health of the community. It would be lamentable indeed if science should thus come to override sympathy. There is not proof

that phthisis is in any degree at all directly communicable; and the fact of the great prevalence of the disease, instead of confirming this doctrine, rather militates against it; for who then would be free from a contagion so universally disseminated?

. Lastly, the methods whereby the specific nature of the tubercular bacillus has been demonstrated, although apparently open to the trenchant criticism bestowed on them by Dr. CREIGHTON, are precisely those which have been pursued with respect to other diseases that are infective and inoculable. The debate was enriched by the demonstration given by Mr. WATSON CHEYNE, and we may well leave the explanation of these methods in his hands. The real question of a tubercular virus, and its infectivity remains, however, untouched, whether the bacillus be the specific virus or not. At any rate we are glad that this debate has taken place. It contained very much more than the subjects we have glanced at; but the general tendency was towards a far greater definiteness and clearness of view concerning tubercle than would have been possible not many years ago. We may be far from the truth yet, and it may be that ideas will vary in the future as much as they have in the past, but when the history of fact and opinion on this subject is reviewed by the light of present knowledge, it becomes evident that, far off from it as we may be still, a distinct advance towards the truth was made by KOCH'S discovery three years ago.

A VERY interesting paper was read at the second general meeting of the Hospitals Association on Jan. 21st, by Mr. C. J. RADLEY, on the "Best Plan for establishing Provident Dispensaries in due relation to Hospitals." One of the interesting points in this paper was the frank admission of the practical failure of the Metropolitan Provident Medical Association. This Association never deserved to succeed, and for two reasons. First, it proposed a very cheap medical service for anybody who liked to apply, without discrimination or inquiry as to means. Secondly, it spent much of its energy in wooing the Friendly Societies, trying to induce them to enter wholesale into its scheme, which would have involved the extensive dislocation of many creditable existing arrangements and relations between clubs and their medical advisers. To cater for the Friendly Societies, as we have always pointed out, was to take coals to Newcastle; and to propose indiscriminate admission of every class to the advantages of cheap terms of medical attendance—terms only proper in the case of those of straitened means—was an obvious and unpardonable injury to the medical profession.

Another point of interest in Mr. RADLEY'S paper is his clear perception of the objections to tampering with the purely charitable character of hospitals by a semi-commercial system of charging out-patients. He thinks such a system would tend to increase the numbers applying, that it can only with difficulty be applied in institutions essentially charitable, and that if applied it could not be expected that those now giving their professional skill would refrain from claiming some share of the revenue. Here, again, we rejoice to see the growing perception of views which we have persistently held. Our hospitals must not become open shops for the cheap sale of medicines and of medical advice. Anything more degrading to our hospitals or more disastrous to the medical profession we can scarcely imagine. It is necessary to speak plainly on this point, for the Metropolitan Counties Branch of the British Medical Association is organising an attempt to elicit the support of the profession in London to a system of payment by out-patients. True, in the report of the subcommittee, the principle is advocated in a very guarded manner: "A small payment should be exacted *for medicines*, not for *medical advice*." This is a fine distinction, and one which will not be made by persons who use hospitals. If any person is to go to a hospital on condition of paying a small sum for medicines, and to be free of the risk of being charged with abusing a charity, woe to the large section of the medical profession who live, and live most creditably, by hard and zealous work among the humble but honest sections of the community, of whom it may be said, as of ROBERT LEVETT:

> "The modest wants of every day
> The toil of every day supplied."

There is reason to believe that the profession is quite alive to the tendency of this system, and that the answer to the questions of the Metropolitan Branch will be clear and unequivocally adverse to the views of the subcommittee.

We are now brought to Mr. RADLEY'S suggestions for remedying acknowledged evils in the uses of our medical charities. Leaving Friendly Societies to themselves, he advocates the formation of a chain of local medical centres throughout the metropolis for the treatment of those unable to pay ordinary fees on some special terms within their means. Each of these centres should have an inexpensive establishment for the dispensing of drugs, receipt of payments, work of registration, &c.; the medical staff to fix the hours for being seen at their own houses. On these local centres, which are supposed to be worked by honorary lay secretaries, would devolve the work of recommending out-patients to hospitals, and Mr. RADLEY would demand of the hospitals to refuse admission to all not so recommended. He would also provide for the small class who might not be able to afford to pay for anything, and yet whom it would be harsh to refer to the parish. His views in the abstract are excellent; but has he rightly gauged the army of honorary secretaries that would be needed, not only with good intentions, but with administrative faculty of a somewhat rare kind? We readily recognise the clearness with which he sees the evils of the existing system, and the scarcely less evils of rival schemes by somewhat careless reformers; but we see little hope of a "chain of metropolitan dispensaries" such as he proposes. We would gladly see some great restriction of the out-patient system; but to open the hospitals on a system of small payments is to demoralise the poor, to wrong the charitable, and to try to destroy the wholesome system by which the humblest working man, if honest, may have the careful attention of a private practitioner.

DR. EDUARDO SALVIA has recently published at Naples a memoir embodying experimental researches on muscle grafting. He recalls that GLUCK was the first to prove experimentally, that muscular tissue detached from a living animal has the power, when introduced into the tissues of another animal, of contracting organic adhesions and continuing to live. He observed that by adopting certain

precautions, chiefly of antisepsis, pieces of muscle, without tendon, might be transplanted in rabbits and hares, and remain in the part grafted as true muscular tissue. If, however, the graft excited inflammatory reaction of some intensity, the histological characters of the engrafted tissue underwent fibrous metamorphosis. In 1882 Dr. HELFERICH, director of the surgical clinique in the University of Munich, sought to put to practical use the knowledge so far acquired by experiments in muscle grafting. His clinical note, published in the *Archiv für Klinische Chirurgie* (Berlin, 1882, p. 562), embodies notes of a case worthy of reproduction. In removing a sarcoma from the front of the right arm of a lady aged thirty-eight, Dr. HELFERICH had been compelled to excise a considerable part of the biceps, which had become infiltrated with the pathological product. Nearly the whole of the upper half of the biceps was removed; only a small bundle of muscular fibres as thick as a slate-pencil being left, on the outer side, continuous with the tendon. The resulting space was exactly filled with a piece of muscle, weighing three ounces and two drachms, detached from the thigh of a healthy dog just at the moment of grafting. Care was taken to ensure accurate adaptation of the muscular surfaces, without bagging; and the grafted muscle was secured to the remaining portion of the biceps with thirty points of catgut suture. Some counter openings were made in the skin for drainage, the external wound sutured, and a Listerian dressing applied. The arm, bent at an acute angle, was fixed to the thorax. The operation was performed with strict regard to antiseptic rules, but without spray. The process of recovery was uneventful. The first dressing was only on the ninth day. In consequence of detachment of some of the sutures, the lower angle of the wound gaped somewhat; and through it issued a necrotised fasciculus of the engrafted muscle, when a carbolised solution was injected through the drainage-tube. The piece of separated muscle was as long as the canine portion inserted, and about one-eighth its depth. On the eighteenth day a piece of skin as large as a shilling sloughed at the point of issue of the mortified muscular fasciculus. A month later, the patient had completely recovered; but the limb was somewhat œdematous. After employing for two months constant and induced currents of electricity, the right biceps muscle regained its normal electro-motor power, alike on the right side, where a part of the original muscle remained, and on the inner side, corresponding to the engrafted muscle. The patient could move the forearm with power, and without the slightest pain, alike in pronation and supination. Dr. SALVIA'S experimental researches were instituted with a view to ascertain if it be possible to transplant muscles between animals differing in species, food, and habits. After a number of failures, he succeeded, under strict antiseptic precautions, in engrafting into the thigh of a dog a portion of the rectus femoris of a rabbit. So perfectly did the transplantation succeed, that no trace of it could be discovered by the naked eye or the microscope, when the dog's thigh was dissected three months later. Reviewing all the steps of his research, Dr. SALVIA has felt justified in formulating the following propositions. First, it is possible to transplant a piece of the muscular tissue of an animal amongst the cut muscular fibres of another animal, although the two may be of different species. Secondly, the piece of transplanted muscle may become thoroughly united with the muscle into which it is grafted, without exciting suppurative or specific inflammation. For the attainment of this result, it is necessary that the piece of transplanted muscle should completely fill the space resulting from the retraction of the ends in the excised muscle. It is equally necessary that the operation be carried out with the strictest antiseptic precautions. Thirdly, the union, between the fibres of the transplanted muscle and those of the animal grafted, takes place by new formation of young muscular fibres; these become immediately continuous with the fibres of the animal and of the graft, without leaving any trace of the primary point of separation.. Fourthly, the grafted muscular fibres gradually lose their distinctive anatomical characters, acquiring those of the animal's fibres in which they live; no difference between them can, after a certain time, be detected by the most careful microscopical examination. Fifthly, the function of the muscle after the graft is perfectly restored, and that comparatively quickly, without the slightest indication of weakness or torpor.

THERE seems no doubt about the fact that we are committed to a much more democratic form of Government than any of which we have had experience hitherto in this country. This is not a party question. Whether it be a subject for credit or for reproach to our leading statesmen is a matter on which our readers will be divided in opinion. But it is important to notice that, as we have already pointed out, the change is one consented to and arranged by a new operation in legislation—viz., a consultation of leading statesmen on both sides. It is not yet definitely ascertained whether Mr. GLADSTONE or Lord SALISBURY got most of his own way in the details, or which party will gain most by the result. It is certain, however, that both were consenting parties to the new democratic constitution of England, and that that constitution is as good as settled. Sensible men of all classes will do well, therefore, to accept the fact and to make the best of it. The medical profession ought not to suffer by the change. Ours is the profession of the future. In its object it is thoroughly human and Christian. Its services are quite as indispensable to the poor as to the rich. It is brought into almost domestic relations with every class of the community. The poor, who do not know the luxury of having a lawyer, and who too often look suspiciously on the minister of religion, eagerly invoke medical aid in the great emergencies of life. The progress of events only enlarges the sphere of its influence and multiplies the occasions for its being consulted. Hitherto the practitioner has been looked to only to cure disease; now he is expected to undertake its prevention. It can scarcely be that the profession, which has so much to do with the people, should suffer by constitutional changes which give the people more power. It will not suffer if it act wisely and honestly with the people. On the contrary, it may attain to new political influence for its own good as well as that of the State. Some objector may possibly refuse to be comforted. He will think of all the natural and inherited stupidity of "HODGE," and of the almost parallel intellect of the lower section of the working classes

in towns, and despondingly refuse to take any pains to conciliate or to educate either of them. It is against this mood that, in the interest of the profession, as in that of the nation, we write. We are well aware that popular constituencies, even now, on great medical questions display very defective intelligence. It is still more sad that learned university professors, in the capacity of candidates for Parliamentary election, should pander to such a state of mind, or rather such an absence of mind. Nevertheless, we, as the popular profession, superintending birth and postponing death, must patiently deal with the democracy till it has undergone that process which Lord BEACONSFIELD himself had to apply to the aristocracy. We must educate. We must give it time. "HODGE" may be in a great fog about vaccination. By the way, "HODGE" in this respect would compare favourably with some of his urban brethren. But we must work for the clearance of the fog both in town and country, and it is certain that, with a little patient reasoning on the part of his friendly doctor, "HODGE" will perceive the bearing of vaccination and many other medical questions as quickly as many of his betters. The masses who are to be enfranchised are also to be educated, not at the Board School, but by their more fortunate fellow-citizens, and we are hopeful of the result. The poor of England are good-natured, easily led, and well aware of the fact that for guidance in political matters they must look to those who know better than they. It will be the fault of the educated and the well-to-do if they do not lead them much as heretofore. It will be a fault of temper, not to say of contempt. But of all men the members of our profession must be on their guard against such an error, and must "gently lead" those who are to be called upon to discharge functions for which they are little prepared, and to express opinions on questions with which they are little familiar.

Annotations.

"Ne quid nimis."

THE EMPEROR OF GERMANY AND SIR JOSEPH LISTER, BART.

THE last honour to Sir Joseph Lister is a very notable one. The Emperor of Germany has conferred on him the "Ordre pour le Mérite" for Science and Arts. Not only is Sir Joseph Lister to be congratulated on this act of the venerable and most illustrious Emperor, but the profession of the United Kingdom will recognise in the act a generous recognition of the claims of British medical science, which it is only fair to say is not new on the part of Germany. The discoverer of vaccination has been more honoured in Germany than in his own country, in accordance with the Scripture that "cannot be broken." The quiet revolution in surgery, involving the practical abolition of pyæmia, hospital erysipelas and gangrene, and an infinite diminution in the calamities of surgery, which we owe to Sir Joseph Lister, more than to any other single man, is a service to mankind not quite on the same scale as the discovery of vaccination, but of very far-reaching consequence. Through the slightly discordant notes of diplomacy it is refreshing to notice the harmony of international grace in the higher regions of science and of humanity. The profession will not fail to notice that the Emperor has found leisure for this act at a time when he has been himself in suffering, from which it is gratifying to know that he is recovering; and they will not think the less of it that it contrasts painfully with the niggard recognition of medicine by our own State.

CANON LEFROY ON THE LUNACY LAWS.

AT Liverpool, on a recent occasion, when preaching for the hospital, Canon Lefroy was good enough to give expression to his views on the subject of certifying lunatics. He recognises the difficult position of medical men, admits the force of the reasons which are rapidly inducing physicians, surgeons, and apothecaries to decline to sign certificates, and he avows that in his opinion "they will be very unwise if they do." Canon Lefroy's suggestion of a scheme to bridge over the time until the Lunacy Laws shall be altered—a totally indefinable period, be it remembered—is that local Health Committees shall appoint specialists to examine and certify, indemnifying them against actions for carelessness. We have nothing to say as to the practical working of this arrangement. Our immediate concern is to express entire appreciation of and sympathy with the views set forth by this eminent and eloquent churchman. We, too, think medical men will be very unwise if they do sign lunacy certificates. By all means let us agree to refuse the performance of this most onerous service. It is one for which medical men receive scant thanks from anybody; and it is one in the doing of which they incur most formidable risks. After recent experience it must be plain to every member of the profession that to sign a certificate is to do an act which may, after long years of forgetfulness, suddenly rise up against the practitioner, involving him in heavy loss, ignominious bullying in a witness-box, and, perhaps, draw down reproach and discredit on his name and pain and penalty on his family. Let us, one and all, stoutly and finally refuse to sign lunacy certificates, and then the law will have to be altered. It would be wrong, socially and morally, to refuse our help to the sick and sorrowing; but in this matter of signing certificates we do no wrong to anyone by refusal. Certifying is not a medical function: it is not helpful to the insane, nor is it a service to society. By continuing to certify, we are simply playing into the hands of those who desire to perpetuate a state of the law which is detrimental to the best interests of the community, and which is adverse to the sufferers from mental disease, and insulting and injurious to the profession we represent and to which we belong. This is our advice, and we hope to see it generally accepted and acted upon by the many, as it is already by the few. As the law now stands, the effect of refusal will not be to prevent, or throw obstacles in the way of, the proper treatment of lunatics, but simply to compel their being placed under treatment at home by *general* practitioners, where and by whom we believe they will be most promptly and successfully treated, until such time as they can, if needful—which it will *not* be in the great majority of instances,—be judged insane after a legal inquiry before a Master in Lunacy.

OVER-PRESSURE IN ELEMENTARY SCHOOLS.

THE January number of the *Westminster Review* contains an interesting article on this subject, in which the recent controversy, arising out of Dr. Crichton Browne's report and the official rejoinder, is ably and, on the whole, fairly criticised. Our contemporary does not approve Dr. Crichton Browne's recommendations; and he is not in favour of aid to feed the children of the poor, or of medical inspection. Meanwhile, he does approve the appointment of a *Royal* Commission of Inquiry, and affirms that such an inquiry, after all that has been said and done in the matter, is absolutely indispensable. There we entirely agree with him.

GENERAL STEWART'S WOUND.

THE news that the gallant General who has won such great distinction by his rapid march across the desert and his brilliant victories over the Arabs has himself sustained a severe wound has been received with great grief on all sides. At present the information as to the nature of the wound is most meagre. It is only known that it is a bullet wound in the abdomen, and that the latest report is to the effect that he is doing well. Bullet wounds of the abdomen are necessarily very dangerous; even when not perforating the peritoneal cavity, they may be attended with contusion of the viscera, and be followed by burrowing suppuration, with all the risks of septic infection and secondary peritonitis. If perforating, the primary danger is from hæmorrhage; and as the latest news is favourable, we may believe that this danger is passed. Should none of the hollow viscera be wounded, the result of the injury will chiefly depend upon whether the wound is kept free from all septic changes. On the other hand, a lesion of a hollow viscus is nearly certain to lead to escape of its contents and fatal peritonitis. In addition to these dangers, the case of President Garfield reminds us that around a retained bullet slow ulcerative changes may be set up, which may lead to the most serious consequences. It is of hopeful import that the second and latest report speaks of some improvement; and it is very fortunate that the gallant patient has been removed on board one of the Nile steamers, where he will be in much more favourable conditions for recovery than in the desert. We shall anxiously await the reports during the next few days. Each day passed safely improves the chances of recovery in geometrical proportion, for it is immediately after the injury that the most serious complications—hæmorrhage, foul gastric and urinary extravasation, and septic inflammation and absorption—are most likely to occur.

MEASLES IN CARDIFF.

ONE of the most interesting and important problems awaiting the solution of scientific sanitarians is the discovery of the laws which govern the variable fatality of outbreaks of epidemic disease. How far does the fatal incidence of such diseases depend upon what, for want of a better term, may be called the sanitary condition of the population attacked, and how far upon varying types of the disease itself? From this point of view the present remarkably fatal epidemic of measles in Cardiff has more than a local interest. No death from this disease occurred in Cardiff during 1884 until the last week of September, when one fatal case was recorded, and five more were registered in the fourth week of October, when the epidemic assumed fatal proportions. Ninety-six deaths from this cause occurred between the middle of October and the close of the year, and fifty-three more during the first three weeks of this year. Thus no fewer than 150 deaths have resulted from measles in Cardiff, practically within three months. With a view to estimate the present sanitary condition of Cardiff, the following figures may be noted. The recorded death-rate in the borough during last year was equal to 24·2 per 1000 of the estimated population, which, if corrected for difference of age and sex proportions in order to compare with the rate in England and Wales, becomes 26·2. The death-rate from the principal zymotic diseases was equal to 4·7; this excess was partly due to the mortality from measles before referred to, partly to the fatal prevalence of scarlet fever during the greater part of the year, and partly to the high rate of infant mortality from infantile summer diarrhœa. These facts point undeniably to unsatisfactory sanitary conditions, but scarcely account fully for the exceptional rate of mortality now prevailing in the town mainly due to the measles epidemic.

UNWHOLESOME MEAT.

A FEW days since, at the Hammersmith Police-court, Mr. Paget heard a summons, taken out at the instance of the Fulham Board of Works, against a butcher for exposing for sale five flanks of beef which were alleged to be unfit for human food. Dr. Collier, the medical officer of health, who was corroborated in his evidence by Dr. Alderson, deposed to having examined the meat. He found it in a state of decomposition and exhaling an offensive odour. In his opinion, the animals had not bled at the time of death. For the defence Dr. Kelly stated that the meat was as sound as any he had ever seen. It had bled, and was well fed. Meat suddenly thawed had a soft, flabby appearance. Unable to reconcile the conflicting views of the doctors, Mr. Paget had to decide the case on his own judgment as to the value of the medical evidence on the two sides. Eventually he imposed a fine of £10. We are not in a position to say whether the conviction was equitable, as that would necessarily presuppose a knowledge of all the facts. At the same time, we maintain the magistrate exercised a wise discretion in giving preference to the story told by the prosecution. On the face of it, it was somewhat improbable that good wholesome meat could be bought at the low price of 4½*d.* per lb. It is much to be regretted there was such a want of agreement as to whether the appearance of the meat was simply due to a sudden fall of temperature or to putrefactive changes in the carcases of animals that had died from disease. No doubt the colouring matter of muscular fibre is liable to be set free and diffused by marked and rapid alterations in temperature, but the consequent staining of the fat never reaches the extent found in meat decomposed and full of blood. We are further at a loss to understand why the question of putrefaction was contested; surely it required no special scientific knowledge to enable one to solve the problem. If, as Dr. Collier testified, foul gases were evolved, there ought to have been an end to the controversy. Notice of appeal against the magistrate's decision has been given.

MISMANAGEMENT OF CONTAGIOUS DISEASE.

A SINGULAR incident occurred in Lambeth a few days ago. A married man, a lodger, was attacked with small-pox and removed to a hospital. His wife, who remained in their apartment, refused to have it disinfected, and was unable to pay the rent due by her. A broker was called in, the lodger's property removed, and the room disinfected. The evicted woman meanwhile had, by the advice of the broker, who was not informed of the facts of the case, applied at the workhouse for maintenance for herself and children. The parish authorities, in their turn, on learning the character of the husband's illness, sent back the whole family with their belongings to the now freshly purified house. It would not be easy to find a more complicated example of bungling from the want of a little ordinary care and patience. The primary error, of course, was the woman's in refusing to allow disinfection. Possibly the omission to include herself and her possessions in the general cleansing which was afterwards accomplished was her fault also. The householder, on his side, neglected to inform the broker—who, for aught he knew, was susceptible to the disease—of the fact that small-pox had been in the house. The parish officials appear to have been misled rather than careless, though a closer inquiry would no doubt have guided them to more judicious measures than those which they adopted. The whole trouble and risk would have been avoided had the householder exercised his authority and judgment by insisting on the purification of his room and its tenants as paramount to the question of rent for the time being, and had then if necessary, but not till then, resorted to the broker. It seems strange that no mention is made of

any injunctions to this effect on the part of the medical officer who sanctioned the removal of the patient to hospital. Such a case as this, if officially notified, should have been attended with other results.

FILIPPO PACINI.

AMONGST the anatomists of this century few have established a clearer title to lasting fame than did the discoverer of the Pacinian corpuscles. One of his attached pupils, Dr. Aurelio Bianchi, has just published in *La Medicina Contemporanea* a life sketch of the distinguished histologist, with the welcome promise of a complete biography, based on original documents. Filippo Pacini was born on May 25th, 1812, at Pistoja, a town of about 12,000 inhabitants, eighteen miles from Florence. He was one of a numerous and poor family, and was destined by his parents for the Church. But he soon exhibited a strong liking and aptitude for the natural sciences, and worked indefatigably in the dissecting-room and in the hospital. Pistoja could not then boast of a microscope; and Pacini constructed one, with a wooden tube and a system of lenses of his own arrangement. Examining the tissues with this rude instrument, he discovered the structure of the corpuscles with which his name is identified. He soon received an appointment to teach microscopy in the University of Pisa, and later on in the school of Florence; but while foreigners were profuse in his praise, the majority of his countrymen appear to have done him scant justice. It was only in 1862, when the celebrated physicist Matteucci became Minister of Public Instruction, that Pacini was supplied with microscopes and teaching apparatus, for which he had hitherto applied to the authorities in vain. His reseaches on the minute structures of the retina and on the electric organ of the torpedo are well known; and we recently gave an illustrated abstract of the researches on cholera, in which the Italian delineated vibrios closely resembling, if not identical with, the comma bacilli of Koch. Pacini died at Florence on July 9th, 1883, according to his biographer, surrounded by only a very few devoted friends, and harassed by the envy of many detractors. This is a charge which we hope may not be sustained by the evidence of the promised complete biography. It is pleasant to recall that Pacini had one great enjoyment in his beautifully situated laboratory and study. They looked on to a lovely little garden at the rear of the great Florence Hospital, a place where a worker imbued with the true philosophical spirit might treat present envy with indifference, while calmly waiting the unerring judgment which impartial time awards to intrinsic merit.

TOO READY TO ATTACH BLAME.

IN last week's issue of a Society journal there is a paragraph professing to describe how the authorities of the Middlesex Hospital manage "not to save life." And as the writer evidently misunderstands completely the real duties of a hospital and its relations to the public, it is well to call attention to it. It appears that a girl took a poisonous dose of oil of almonds at a perfumery establishment in Oxford-street. Emetics were given, and a doctor, who was called in, wished to use a stomach-pump. He accordingly sent to borrow one from Middlesex Hospital, and was met with a refusal, "as they did not lend out stomach-pumps." On this flimsy pretext a charge is brought in the journal referred to against the hospital of want of humanity. The smallest knowledge of the position in which our hospitals stand to the public would show any impartial person that they could not for a moment undertake to lend any medical or surgical necessaries of which doctors outside may be in want. We need not point out that, if the above charge be just, it would apply as fairly to a refusal to lend other surgical instruments, drugs, and apparatus of all kinds, and then why not nurses, food, beds, linen? The proper thing to have done in this case was for the attending doctor to have himself provided the suitable means of treatment, or, in default of that, to have sent the patient to the hospital, where it is well understood that all appliances needed for emergencies are immediately at hand. To lend a stomach-pump or any other piece of apparatus might lead to its absence just when required in the hospital, and possibly to its loss altogether. We regret that our contemporary should have made such an obviously unjust criticism upon an institution so well deserving of public confidence and support as the Middlesex Hospital.

HEMIANÆSTHESIA FROM CONGENITAL BRAIN DISEASE.

THE only justification for the title of the paper read at the last meeting of the Clinical Society by Dr. Althaus, an abstract of which will be found elsewhere, appears to us to be on the principle implied in the expression *lucus a non lucendo*. The evidence so pertinently demanded by Dr. Lees of the congenital date of the affection was, in our opinion, not forthcoming; and the questions of Dr. Angel Money and Dr. Adeney implied doubt of the view taken by Dr. Althaus. If the conclusions arrived at by the author of the paper be well founded, we should have in the application of the electric battery a ready means of curing, at all events, *some* of the results of organic disease of the brain, and presumably of other parts of the nervous system. One of the conclusions arrived at by the author was to the effect that a profound loss of all sensation, general and special, was due to the effects of a blood-clot long since absorbed from the region occupied by the posterior third of the posterior segment of the internal capsule of one cerebral hemisphere in a girl aged eleven years. The more we think of the facts of the case the more we are driven to the inference that the case was one of functional, not to say hysterical, hemianæsthesia, the temporary, if not permanent, cure of which is readily explicable by the employment of the electric brush. It is probably true that such an affection is not really of congenital origin, though there is certainly nothing in the age of the child which would preclude the possibility of the occurrence of such functional nervous phenomena.

"VENTILATION ABOLISHED ALTOGETHER."

MR. BARON HUDDLESTON is trying a great sanitary experiment at the Royal Courts of Justice. It is one which will interest everybody, and we hope to be duly informed of the results obtained; indeed, we shall look for information with considerable impatience. The late Lord Derby is reported to have said in reference to some wine recommended to him as a preventive against the gout, that he preferred that disease to the beverage that promised immunity. Mr. Baron Huddleston prefers to be unventilated rather than have cool air blown on him from every quarter under pretence of purifying the chamber in which he is doomed to sit. The engineer is enjoined, on peril of contempt of Court, not to ventilate Mr. Baron Huddleston's court any more. It will be curious to note whether the strictly local death-rate of that particular Court rises or falls. We should like to receive a weekly bulletin of health and mortality, countersigned by the judge himself. Will he oblige us? The stagnant atmosphere of this individual chamber might also be turned to useful account as the raw material out of which to manufacture a vast marketable supply of specimens of mephitic vapour. We trust the analytical chemists and physicists will not allow it to remain unutilised. It is a pity the idea is not to be carried a little further, and that a portion of the Royal Courts of Justice cannot be freed from the nuisance of drains, artificial water-supply, artificial lighting appliances, and so on. It might even be interesting

to put the hands of the clock back in other senses, to try the effect of reversion to an earlier developmental type, so that the pristine glories and conveniences of a previous age could be studied in their entirety side by side with the so-called "advantages" of modern applied science. We fear the idea is not altogether original. At the Health Exhibition insanitary houses were exhibited for comparison with the sanitary buildings and appliances which the public were to be incited to emulate. In olden times wise men made their slaves drink to excess as a warning to their sons. It has however, been left to Mr. Baron Huddleston to exhibit a court of law in the Royal Courts of Justice in which "ventilation is to be altogether abolished."

"HOW TO REDUCE WEIGHT."

DO not try it. The *Field* is anxious to induce hunting men to adopt measures to reduce their weight for the saddle. This is our advice on the subject: Rest assured no measure will suffice which is not injurious to health. One man will put on weight with very little food, while another will undermine his stability by a reduction which appears moderate. The simple but golden rule is to eat *slowly* and masticate the food taken thoroughly, so that there may be time for the organism to make known its satisfaction with the supply placed at its disposal before the stomach is overloaded. The mistake made by hunting men and others, who, to use a common expression, "are as hungry as hunters," is that of coming home exhausted and eating ravenously. By this haste no time is allowed for the organic needs of the eater to cry, "Hold—enough!" It is like emptying a whole scuttleful of coal on the fire when it is only in need of a few dexterously placed lumps. The digestive organs being in fairly good working order, the repletion is not resented as it would be by a weakly "dyspeptic," and muscle and fat are laid on in excess. If we only ate more deliberately we should find half our accustomed quantity of food sufficient to satisfy the most eager cravings of hunger. What we call "appetite" is a most misleading sensation. It is only remotely related to the actual demands of the organism. Let hunting men, and men of all classes who lead healthy active lives, resolve to eat and drink *slowly*. With this single precaution they will soon find that the tendency to "weight" diminishes, while the appetite being disciplined unconsciously by the formation of the habit, it will be needless, as it is useless, to live by rule as regards the nature or quality of the food taken.

ENTERIC FEVER IN ABERDEEN.

DR. SIMPSON, medical officer of health, has prepared a special report on an outbreak of enteric fever attacking sixty-five persons in fifty-six families in the city of Aberdeen. Some few were, perhaps, not concerned with the special outbreak—two, indeed, were imported cases,—but at least forty-three are set down to the same cause. Drainage and water being obviously excluded, milk infection was found to be the only explanation, but it is a curious circumstance that the outbreak involved more than one dairy. At one of these dairies a young woman, who had up to one or two days previously been serving milk which was sent into Aberdeen, was found ill of the disease. As regards two other dairies that are in question, no such distinct source of specific infection was discovered; but assuming the possibility of an importation of the infection or of its retention about the premises, the sanitary circumstances of the dairies were such as to favour the contamination of the milk. Thus, at one large cesspools of foul stuff were found lying stagnant within two feet of the dairy window. The case is in some respects not quite so clear as regards the two latter dairies as it is with regard to the first one named, but milk appears to have been the only thing that those attacked had in common. At the first dairy it is stated that no fault lay with the dairyman, and until Dr. Simpson investigated the case the patient discovered there was not supposed to have fever. Dr. Simpson rightly adds that it is a good thing for those who use milk to have it thoroughly boiled.

SKILLED OPINION.

OUR generally sagacious contemporary, the *Globe*, has somewhat muddled the argument it would fain advance against our view of the competency, or rather the incompetency, of magistrates to diagnose mental disease. It is contended that, as doctors differ, experts, not in physic, but in the law of evidence, must be called in to decide between them. This is amusing in itself as an independent proposition, but it is more amusing still when it comes to be applied to the case in point. A magistrate before whom a lunatic is brought to be certified is not in a position to apply the law of evidence, because there is only one witness before him—namely, the single medical man, or rather the single medical certificate. Apparently, our contemporary is not aware that when there are two experts engaged and two certificates the case cannot come before a magistrate at all. Whenever an alleged lunatic is brought before a justice of the peace, it is for this dignitary to form an independent opinion as to his sanity or insanity. It is wholly and solely because there is no second medical certificate—as in the case of a pauper—that the magistrate—or clergyman, if there be no magistrate at hand—is asked to act. When there are two certificates magistrates cannot legally interpose. Surely this ought to be known.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund was held on the 23rd inst. at the Mansion House, Sir Sydney Waterlow, Bart., M.P., in the chair, for the purpose of electing committees and officers for next year. The members of the General Purposes Committee were re-elected, with the exception of the late Bishop Claughton, the name of the Rev. Dr. Allon being added. The members of the Committee of Distribution were also re-elected, with the exception that Mr. F. H. Norman, banker, was substituted for the late Mr. Jervoise. Sir E. H. Currie and Mr. R. B. Martin were reappointed hon. secretaries, and Mr. H. N. Custance was re-elected secretary. A resolution, moved by the chairman and seconded by Sir W. McArthur, M.P., that the Council record on its minutes the deep sense of regret they felt at the loss sustained in the death of the Bishop of London, was unanimously agreed to, after which, there being no further business to transact, the meeting separated.

CHOLERA ON THE BOLAN ROUTE.

WE learn from the Calcutta *Englishman* that a serious outbreak of cholera occurred shortly before the mail left amongst the men of the North Staffordshire Regiment on their way down the Bolan Pass. The two wings of this regiment started from Quettah on the 3rd and 4th inst., and, marching by single stages, they reached the foot of the pass on the 10th and 11th inst. respectively. The troops are said to have been "seasoned" men who had returned from the Zhob Expedition. The extremes of temperature are not great at the stage they reached. The foot of the pass is not, we should think, a favourable spot for cholera, the ground being dry and rocky, and the air blown from the mountain wilderness is pure and bracing; also, the water of the river here is quite pure to outward appearances. It is at this spot that cholera showed itself first. Ten cases occurred in one wing alone, and in all twenty-three ter-

minated fatally. Shortly after, we understand, a portion of the regiment, consisting of 400, was send to Landi, in Lower Sind. After this judicious and well-timed step had been taken no fresh case occurred among this body of men. The attack on the whole was of a virulent type. A part of the regiment, some 200, was still encamped at a place called Rindli; their tents were pitched close to the river and at a distance of two miles from the railway station. This regiment had suffered a good deal from the climate and surroundings of Quettah, which are by no means congenial to health.

RHEUMATIC GLOSSITIS.

AN alleged case of rheumatic glossitis is recorded by Dr. Carvallo in *La Cronica Médica*. The patient was a man aged forty, who one day found that his tongue began to enlarge and that articulation was difficult. The swelling increased so much that the tongue was no longer confined in the limits of the mouth. There was much difficulty in breathing; the lips were blue; the pulse was small; salivation was incessant; deglutition was painful; speech was impossible, and at times attacks of suffocation threatened dissolution. Leeches were applied to the angles of the lower jaw. Dr. Carvallo remembered to have read in M. Jaccoud's "Traité de Pathologie Interne" that Lawrence had written of the occurrence of glossitis as a consequence of rheumatism. The patient admitted that he had had rheumatism, and that he even then had rheumatic pains about the shoulders. An infusion of jaborandi was prescribed, and afterwards a draught containing salicylate of soda. The next day the tongue had diminished greatly in size, and had returned to the buccal cavity. The suggestion that such cases of swelling of the tongue may depend on a rheumatic agency is perhaps valuable; the proof that the case mentioned was of rheumatic nature cannot be said to have been given.

UNUSUAL ACCIDENTS TO ACROBATS.

THE present pantomime season has been marked by more than the usual number of accidents to the performers. Both the clown and the harlequin, aged respectively thirty-five and forty-two, in connexion with one pantomime have had the misfortune to rupture the tendo Achillis. In the former the tendon itself gave way, and in the latter the muscle near to the tendon. Both were making unusual exertion in attempting a jump; and in the case of the harlequin, the injury was possibly aided by striking the back of the leg against a bar, just as he started forward for the spring. At another theatre a still more uncommon accident happened to a girl aged twenty, while dancing in the ballet. In springing forward from the right foot, she felt it twist outwards, and heard a snap, experiencing pain in the outer side of the foot. She was obliged to leave the stage, and on examination it was found that she had fractured the fifth metatarsal bone of the right foot near the distal end.

THE INJURED POLICEMEN.

ON inquiry at Westminster Hospital, we find that the policemen who were injured by the dynamite explosion in Westminster Hall on Saturday last are progressing most favourably. Cole, the man who was carrying the packet just before its explosion, was the more seriously injured, having sustained a fracture of four ribs on the left side, caused by falling in the hole made by the explosion, the other constable, Cox, falling on him. The latter was suffering from slight concussion of the brain and had a contusion under the right eye. He was not long unconscious, and on recovering he manifested considerable mental excitement. Both the patients are still deaf, but the deafness is less marked than it was.

ISOLATION ARRANGEMENTS FOR FAREHAM.

THE Fareham rural sanitary authority have decided to abandon their scheme for erecting a hospital for the isolation of infectious diseases, and the *Hampshire Post* publishes a letter from a correspondent who tenders the newspaper his thanks for having in time given publicity to so ridiculous a scheme, one which would, in his judgment, have affixed a stigma and disgrace upon the town as a hotbed of disease. The ignorance displayed in this letter is great, and if some day Fareham is publicly known as a place to which the "disgrace" attaches of having within it an epidemic, which could easily have been checked at the onset had provision been made beforehand whereby a few first attacks of such disease could at once have been isolated, the writer of the letter in question and his sympathisers may perhaps regret that they expressed opinions so hasty and so foolish. In many a place similar action has come to be regretted.

TANK-WATER AND CHOLERA.

THE memorandum concerning the tank at Calcutta, given by the Cholera Commission in their second report (*vide* p. 221), is directed mainly to the confutation of an inference drawn by Dr. Koch respecting the connexion between an outbreak of cholera amongst the dwellers in the vicinity of a tank and the presence of comma bacilli in the water. Dr. Klein has confirmed the statement as to the presence of the comma bacillus in the water not only of this tank, but in that of two others. In not one instance was cholera then present amongst the two hundred families living around the tank; but in the case of one tank cholera occurred in three houses situated at some distance. When the whole report is published a reply of Dr. Koch to such statements as these will doubtless be made; meanwhile it is interesting to know that Dr. Klein thoroughly recognises the special peculiarities shown by the comma bacillus in cultures, but does not think that these suffice to distinguish it from putrefactive bacteria.

COCAINE IN RECTAL SURGERY.

ON January 27th, at the West London Hospital, Mr. Swinford Edwards ligatured six large hæmorrhoids in a woman aged fifty. As she was the subject of aortic disease, it was decided not to administer an anæsthetic. One minim of a 4 per cent. solution of cocaine was therefore injected into each pile at the muco-cutaneous junction, after which the entire surface of the mucous membrane at the lower part of the rectum was painted over with a like solution. The operation, which lasted twelve minutes, was almost painless, the patient only slightly feeling the last incision. Twenty-five minims of the solution of cocaine were used in all.

THE CHAIR OF PATHOLOGY AT LEIPSIC.

PROFESSOR BIRCH-HIRSCHFELD of Dresden has been nominated to the Chair of Pathological Anatomy at Leipsic, vacant by the death of the late Professor Cohnheim. The new professor is perhaps best known for his exhaustive text-book on Pathological Anatomy, of which the second edition is now appearing. He has done much original work in bacteriological subjects. He is not therefore likely to pursue the physiological line of inquiry so much advanced by the late illustrious teacher.

SCIENCE AT TURIN.

IT has been determined to spend the very liberal sum of £120,000 in creating new scientific buildings in connexion with the University of Turin. Half that sum will be provided by the Provincial and Communal Councils of the City, and the other half by the Government, with the sanction of the Italian Parliament.

THE PATHOLOGY OF CHEYNE-STOKES' BREATHING.

SOME histological alterations in the bulb and pneumogastric nerves, to which changes he attributes the phenomena of Cheyne-Stokes' respiration, have been recently discovered by Tizzoni. This mode of respiratory rhythm consists in the presence of a prolonged pause followed by respiratory movements, at first slow and superficial, but gradually rising in frequency and increasing in depth, again slowly to decrease. So much misunderstanding has arisen on the subject of what is and what is not meant by this named mode of respiratory rhythm that Tizzoni has done well to state precisely what it is that he meant. In one of his cases there was organic heart disease, and the respiratory phenomena lasted forty days. At the autopsy chronic inflammatory changes were found ascending the vagi, with blood extravasation into the lymphatic spaces of the perineurium and endoneurium. On the left side only the peripheral portion of the nerve was affected, whilst the right nerve was altered along the whole of its course, even to its origin. In the bulb the changes existed in the form of small foci, and were also more marked on the right side. The point where the alterations were most prominent was beneath the ependyma over the longitudinal furrow of the calamus scriptorius. In a second case, which was one of uræmia, the phenomena were observed for several days. The vagi were normal, but the superior half of the medulla oblongata presented lesions similar to those just described, though less pronounced and symmetrical.

THE *Sanitary Journal* of Ottawa contains, in the second number of the seventh volume, an abstract of a very interesting paper read before the American Medical Association, by Dr. Karl von Klein, on Jewish Hygiene. He shows at length how largely the Talmud is pervaded with regulations having a distinct sanitary bearing, and that, mixed up with the many childish, fabulous, and irreverent things which are included in the code, there still remains that which forms the basis of many of our most modern sanitary measures. Whether the regulations relate to cleanliness, morality, preparation of food, or otherwise, many of them are pregnant with hints which deserve to be far better known than they are.

IN consequence of the prevalence of small-pox in and about London, visiting at the Surrey County Asylum, Brookwood, has been prohibited until further notice, and the medical superintendent has deemed it necessary, as a precautionary measure, to have the patients and staff revaccinated. A difficulty being found in procuring a ready and sufficient supply of lymph, the public vaccinator for the district, Mr. T. Cawley Eager, of Woking, on being consulted in the matter, kindly offered to perform the vaccination with the assistance of the medical officers of the asylum. The result has been excellent; nearly 1200 persons were revaccinated, and about 80 per cent. of the cases have proved successful.

THE Executive Council of the Irish Medical Association have forwarded to the Secretary of State for the Home Department a memorial praying for a further inquiry into the case of David Bradley, who was recently convicted at Leicester of criminally assaulting a female patient. The memorialists express the opinion that the evidence of the prosecutrix respecting the circumstances of place, time, and position under which the offence is alleged to have been committed is altogether incredible, and that such evidence is rather contradicted than corroborated by the testimony of other witnesses produced.

DR. ENSOR, district surgeon at Port Elizabeth, in a letter to the *Port Elizabeth Telegraph*, relates a case of alcoholic poisoning successfully treated by the subcutaneous injection of one-fifth of a grain of apomorphia, which he states is interesting as an instance of life saved by the prompt administration of a new remedy for narcotic poisoning, especially when insensibility is too complete for the administration of an antidote by the usual route.

IN the action brought by the Earl of Jersey against a publican named Woodward and the Uxbridge Union Rural Sanitary Authority in respect of a nuisance caused by the pollution of the Osterley stream, Mr. Justice Kay, on the 26th inst., granted a perpetual injunction against the sanitary authority, ordering them to pay to the plaintiff his costs of the action, and dismissed with costs the case against the defendant Woodward.

IT is stated that the Local Government Board have appointed Dr. Davies, one of their medical inspectors, to visit all the towns on the south-east coast, for the purpose of holding inquiries into the sanitary arrangements of each place, and especially as to the means at command for preventing the spread of infectious diseases.

SECOND REPORT OF THE SPECIAL CHOLERA COMMISSION IN INDIA.

THE Supplement to the official *Gazette of India* contains the following documents in continuation of the memorandum published a short time ago by the Special Cholera Commission in India:—

From Surgeon-General J. M. Cuningham, M.D., Sanitary Commissioner with the Government of India, to the Secretary to the Government of India, Home Department. (Dated Calcutta, Dec. 9th, 1884.)

In continuation of my letter of the 27th ult., I have the honour to submit, for the information of the Government, the accompanying communication from Dr. Klein, and to suggest that it also may be published in the Supplement to the *Gazette of India* for general information.

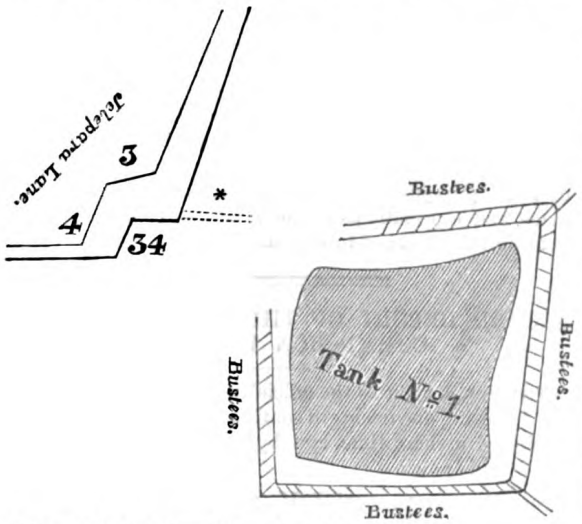
The fact that comma bacilli have been found in tanks without any case of cholera having occurred among the large number of people using them is an observation of much interest and importance in regard to the relation of comma bacilli to cholera. The observation has a special interest and importance, moreover, from the circumstance that one of the tanks in question is the *same tank* as that in which Dr. Koch found comma bacilli, and so hastily concluded that the outbreak of cholera which took place about that time among persons using this tank had been caused by the comma bacilli it contained.

From Dr. E. Klein, to the Sanitary Commissioner with the Government of India. (Dated Calcutta, Dec 3rd, 1884.)

In addition to the short memorandum signed by myself and Dr. Gibbes, which we had the honour to submit to you some days ago, I append here some interesting notes with regard to the relation of comma bacilli in tank water to cholera in Calcutta, which were collected in conjunction with Dr. D. D. Cunningham.

An outbreak of cholera occurred between Nov. 14th and 16th in three houses in Jelepara-lane in Calcutta. The houses are marked in the subjoined plan as No. 34, No. 3, and No. 4. In No. 34 occurred three, in No. 3 two, and in No. 4 three cases. Those of No. 34 were the first. The only condition common to all these houses is this, that in front of them is an opening of the sewer passing under the street. A passage marked * on the plan leads at some distance to a large tank, No. 1, around which is a number of bustees. The people of these bustees use, as is generally the case, this tank for all kinds of purposes, cesspools, washing of clothes, utensils, and drinking. The above three houses, Nos. 3, 4, and 34 of Jelepara-lane, are inhabited by well-to-do people, and they have in their houses a good and pure water-supply of their

own, and their inhabitants never come near the tank at all. The water of this tank is very dirty, and contains undoubted comma bacilli, exactly like those found in choleraic evacuations. Although a large number of the natives living in the bustees surrounding this tank constantly use and drink this water, no case of cholera has occurred amongst them. As you are aware from Dr. Koch's official reports to his Government, this gentleman visited during his stay in Calcutta (February 13th and 20th, 1884) bustees in Sahib Bagan, amongst the inhabitants of which there occurred, between January 21st and April 27th of this year, a severe outbreak of cholera. These bustees are located around a tank which for convenience sake may be here called No. 2. There are about two hundred families living around this tank, and, as is usually the case, the utilise this water for washing, bathing, cleaning, and drinking purposes. In this



* Passage leading from Jelepara-lane to tank.

water Dr. Koch found the comma bacilli, and he quite arbitrarily concluded that they caused that outbreak of cholera. I visited this tank lately and found in its water undoubted comma bacilli. There has occurred, during the whole of November, 1884, one single case of cholera, although about two hundred families use the water. Close to this tank there is another tank, No. 3, and around this live also about two hundred families. As in the former case, the people here around tank No. 3 use the water for all purposes, including drinking purposes. The water of this tank is dirty, and a sample taken close to the shore revealed undoubted comma bacilli. There has not occurred a single case of cholera in these bustees during the whole of this year. It is worth stating that there is a communication between tanks Nos. 3 and 2, there being a slight flow from the former into the latter. Tank No. 2 receives water from the ice-factory close by.

THE REPORT OF MR. L. WRAY, JUN., ON COLLECTING AND PRESERVING VACCINE LYMPH.

THIS report, which is addressed to the Assistant Resident at Perak, urges the need for more attention being devoted to the preservation of vaccine lymph. The report deals solely with the method of storage in tubes, and in it Mr. Wray points out that he has examined under the microscope tubes of lymph sent from England to the Government of Perak, and that he has "found some of them to be swarming with septic bacteria, and as a result void of *micrococcus vaccinæ*, and quite useless for purposes of vaccination." This is a reasonable ground on which to base his argument; but when he adds that such tubes "are constantly touched by hands that have, perhaps, only a few minutes previously been feeling the pulse of a fever-stricken patient or dressing sores of the most loathsome character," we should prefer to rely upon the rejection of lymph from persons guilty of such culpable carelessness, rather than upon the process of cleansing and sterilising the tubes.

Mr. Wray describes the apparatus with which he effects his object to be a glass tube dilated in one part, and closed at its lower end by a piece of indiarubber tubing, pinched by a pinchcock; the tube is filled with water, and the capillary lymph tube, after the latter has been filled with strong acid, has one end inserted into a pinhole in the indiarubber and the water is then forced through it. Subsequently, the capillary tube is dried in an oven and placed with others in a glass tube, hermetically sealed at one end and closed with cotton-wool at the other. The whole are then exposed to a high temperature to sterilise them.

Mr. Wray gives us no definite information as to comparative results with lymph tubes sterilised and with those filled without these precautions. A series of careful experiments with lymph taken at the same time would have a considerable value in determining their worth; and at the same time it might be well to compare the results with those obtained by lymph stored in points or in other ways. It must not be forgotten that the destruction of the vaccine organism may come about from causes other than micro-organisms collected from without the body of the vaccinifer, and that the preservation of lymph may be dependent as much upon its growth as on its subsequent exposure to external influences.

CYPRUS.

THE report on the census of Cyprus in 1881, taken under the superintendence of Dr. F. W. Barry, late Sanitary Commissioner of the Island, has just been published as a parliamentary paper. It shows the population to have amounted to 186,173 persons, being in the proportion of fifty per square mile. Of the total enumerated, 95,015 were males and 91,158 females, a preponderance of males which, "although contrary to the experience of all European countries, with the exception of Greece and Bulgaria, has been found to exist to a greater or less extent in all Asiatic countries." The average number of inhabitants to each house was 4·24. Of the whole population 24·4 per cent. were Mahomedans, 73·9 per cent. members of the Orthodox Greek Church, and 1·7 per cent. belonged to other denominations.

Under the head of "infirmities of the people" we find that the number of blind amounted to 12 per 1000 of the population, the average in England and Wales being only ·88 per 1000. This very high proportion is believed to be chiefly a result of the great prevalence of ophthalmia and, until recently, of small-pox, but is also in some measure due to the unwholesome surroundings and condition of the dwellings and to the want of personal cleanliness. The proportion of deaf mutes in the population is 1·2 per 1000, or double the ratio in England; and of persons of unsound mind (including lunatics, idiots, and imbeciles) 3·0 per 1000; but there is reason to believe this has been rather understated. It corresponds very closely with the ratio in England and Wales, which by the last census was shown to amount to 3·26 per 1000. There were 78 persons returned as affected with leprosy, of whom only ten were under twenty-five years of age. Dr. Barry remarks that there can be little doubt the number of lepers has been understated. "In Cyprus the leper, when recognised as such, is doomed by custom to social extinction. His property, if he has any, passes to his next of kin; he is an outcast from society, even from his nearest relatives; he can hold no official position, and even the offices of the church are denied to him. Under these circumstances it is a matter for surprise that so many as twenty-eight persons outside the leper farm have declared themselves to be affected with this loathsome disease." Of the lepers only two were returned as Mahomedans, the rest being members of the Greek Church.

THE PARKES MUSEUM.—The Council has received a number of interesting articles and models from the Japanese Section of the Health Exhibition, and at the special request of the Japanese Commissioner they have sent a large case of selected duplicates from the Museum to the Home Department at Tokio. The Council has also received the valuable collection of books in the health section of the library of the International Health Exhibition.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6231 births and 4091 deaths were registered during the week ending the 24th inst. The births exceeded by 417, and the deaths by 464, the average weekly numbers during 1884. The annual death-rate in these towns, which had been equal to 24·9 and 24·2 per 1000 in the preceding two weeks, further declined to 24·0 last week. During the first three weeks of the current quarter the death-rate in these towns averaged 24·4 per 1000, against rates declining steadily from 28·1 to 21·3 in the corresponding periods of the six years 1879-84. The lowest rates in these towns last week were 16·4 in Brighton, 17·6 in Blackburn, and 18·0 in Derby. The rates in the other towns ranged upwards to 29·9 in Leicester, 30·3 in Norwich, 34·9 in Wolverhampton, and 40·9 in Cardiff. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 372 and 370 in the preceding two weeks, rose again to 372 in the week ending last Saturday; these included 112 from whooping-cough, 69 from measles, 47 from scarlet fever, 46 from small-pox, 38 from "fever" (principally enteric), 32 from diphtheria, and 28 from diarrhœa. These diseases, in the aggregate, showed the lowest rate of mortality last week in Blackburn and Birkenhead, and the highest rates in Preston, Leicester, and Cardiff. The highest death-rates from whooping-cough occurred in Bristol, Birmingham, and Leicester; from measles in Sunderland, Leicester, and Cardiff; from scarlet fever in Newcastle-upon-Tyne; and from "fever" in Wolverhampton, Norwich, and Derby. The 32 deaths from diphtheria in the twenty-eight towns included 12 in London, 5 in Liverpool, 2 in Bristol, and 2 in Bradford. Small-pox caused 61 deaths in London and in its outer ring of suburban districts, 1 in Birmingham, 1 in Liverpool, and 1 in Bolton. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1001 and 1009 on the preceding two Saturdays, further rose to 1092 at the end of last week; the admissions also rose to 287 last week, from 234 and 216 in the previous two weeks. The Highgate Small-pox Hospital contained 99 patients on Saturday last, 25 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 609 and 552 in the preceding two weeks, further declined to 513 last week, and were 24 below the corrected weekly average. The causes of 93, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Derby, Bolton, and Halifax. The largest proportions of uncertified deaths were registered in Birkenhead, Huddersfield, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 30·7, 30·5, and 29·0 per 1000 in the preceding three weeks, further declined to 28·5 in the week ending the 24th instant, but exceeded by no less than 4·5 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 20·1 and 20·5 in Edinburgh and Leith, to 32·2 in Glasgow and 35·4 in Dundee. The 695 deaths in the eight towns included 29 which were referred to whooping-cough, 26 to measles, 11 to diarrhœa, 9 to "fever" (typhus, enteric, or simple), 6 to diphtheria, 5 to scarlet fever, and not one to small-pox; in all, 86 deaths resulted from these principal zymotic diseases, against 110, 94, and 83 in the preceding three weeks. These 86 deaths were equal to an annual rate of 3·6 per 1000, which was 1·4 above the mean rate from the same diseases in the twenty-eight English towns. The 29 deaths from whooping-cough in the Scotch towns showed a slight decline from recent weekly numbers, and included 9 in Glasgow, 5 in Dundee, 5 in Leith, and 4 in Greenock. The fatal cases of measles, which had been 26 and 20 in the previous two weeks, rose again to 26 last week; 16 occurred in Glasgow, 5 in Dundee, and 3 in Aberdeen. The 11 deaths attributed to diarrhœa, of which 5 occurred in Glasgow and 4 in Dundee, were 6 below the number in the corresponding week of last year. The deaths referred to "fever," which had been 5 and 12 in the preceding two weeks, were 9 last week, and included 3 in Glasgow, 3 in Edinburgh, and 2 in Aberdeen. Four of the 5 fatal cases of scarlet fever and 4 of the 6 of diphtheria were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had declined from 231 to 174 in the preceding three weeks, rose again to 196 last week, and exceeded by 95 the number returned in the corresponding week of last year. The causes of 114, or nearly 16 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 31·2 and 31·0 per 1000 in the preceding two weeks, rose to 31·9 in the week ending the 24th inst. During the first three weeks of the current quarter the death-rate in the city averaged 31·4 per 1000, the mean rate during the same period not exceeding 23·9 in London and 24·2 in Edinburgh. The 216 deaths in Dublin last week showed an increase of 6 upon those returned in the previous week, and included 23 which were referred to the principal zymotic diseases, against 19 and 23 in the previous two weeks. Of these 23 deaths, 6 resulted from diarrhœa, 5 from measles, 4 from "fever" (typhus, enteric, or simple), 3 from whooping-cough, 3 from scarlet fever, 2 from diphtheria, and not one from small-pox. These deaths were equal to an annual rate of 3·4 per 1000; the rate from these diseases last week was equal to 2·0 in London and 2·3 in Edinburgh. The 6 deaths attributed to diarrhœa showed a marked increase upon recent weekly numbers, and the fatal cases of measles also showed an increase; the deaths from scarlet fever, on the other hand, declined to 3 from 6 and 13 in the previous two weeks. Three inquest cases and 3 deaths from violence were registered within the city; and 64, or nearly a third of the deaths, were recorded in public institutions. The 29 deaths of infants showed a further decline from recent weekly numbers, while those of elderly persons were more numerous. The causes of 38, or nearly 18 per cent., of the deaths in the city last week were not certified.

THE COMMA SHAPED BACILLUS: A ZYMOGENIC, NOT PATHOGENIC, ENTITY?

To the Editor of THE LANCET.

SIR,—On reading Dr. Koch's interesting and careful report on his investigations on Indian cholera, it occurred to me that I had already seen such organisms as are figured in his diagrams in material other than is associated with that disease. I then set to work in the microscopic examination of mucus from the small intestines of persons who had died from ordinary affections, and found curved bacilli, identical in shape, size, and appearance with comma bacilli, in all or nearly all. These bacilli, it is true, are to be found much more abundantly in the flaky mucus so commonly met with in the ileum after death from cholera than elsewhere in the digestive tract, or in this part of the bowel, under other circumstances. But I have found identical organisms in neutral or slightly alkaline urine in similar abundance; and the ordinary mucus even of cholera shows not many more bacilli than are to be seen in the mucus of the small intestines of persons who have died from other causes. Ordinarily, indeed, both as regards cholera and other affections, the intestinal mucus examined under the microscope shows very few curved bacilli and a great number of straight large putrefactive bacteria, micrococci singly, in zooglœa, and in chains, and spirilla. In human urine I found curved bacilli within five minutes of being voided from the bladder. Some six hours later the same urine showed a slight increase in these organisms; and this slow multiplication goes on till the urine becomes neutral or slightly alkaline, when they are to be seen in numbers such as are only elsewhere to be found in cultivations from the flaky mucus already mentioned.

The method of examination I adopt is as follows. A drop of urine from the surface is placed on a glass slide, which is then heated slowly at the flame of a

spirit lamp till evaporation is complete, and after a few minutes the dried residue is covered with a few drops of an alcoholic solution of gentian violet. Five minutes afterwards, the excess of colour is washed off with distilled water, and the slide again heated over the flame of the spirit lamp. I found this second heating absolutely necessary to kill the organisms, many remaining still alive after the first heating and the removal of the excess of colour, showing thus a most remarkable tenacity of life. The preparation may now be studied with a $\frac{1}{12}$ immersion lens, oil or water. A specimen mounted in Canada balsam can be very well studied with a $\frac{1}{8}$ object glass and No. 2 eyepiece. Latterly, I found that methyl blue gives a better result than gentian violet; for, though not so bright a colour as the latter, it somehow defines the micro-organisms more distinctly. It is to be noted, however, that the process of staining is much slower with methyl blue than with gentian violet. Quite recently I got excellent results from using a mixture of equal parts of the two colours. It would appear, then, that curved bacilli are not specifically connected with cholera; at all events, not in the light in which the head of the German Cholera Commission would have these organisms regarded. They are, nevertheless, an indubitable pathological feature of that disease; but this, I think, will soon be shown to be something more in the shape of a consequence than a cause of the malady. An experienced and trustworthy observer like Surgeon-Major Lewis testifies to the presence of comma bacilli in healthy saliva. They can be seen by anyone in healthy urine and in the mucus of the small intestines of those who have died from ordinary diseases, and are thus presumably discoverable throughout the mucous tract under most circumstances. This leads me to the expression of an opinion that has been gaining ground in my mind for some time, which is that the organism in question should be regarded more as a physiological than a pathogenic entity. Dr. Koch's own careful observations lend a measure of support to this supposition. He noticed that a colony of comma bacilli in cultivation to a certain extent dissolved the sterilised proteids on which they were nourished; presumably, the proteids were thus converted into peptones. He noticed also that for some days these organisms multiplied, to the exclusion of all others, in the flaky mucus of cholera kept on linen in a moist atmosphere, and then gave place to those characteristic of putrefaction.

Now, this is exactly what I find in the case of urine; until it becomes markedly alkaline, or, perhaps I should say, till decomposition commences, it shows myriads of curved bacilli, to the exclusion of all other organisms; whilst beyond this point large straight putrefactive bacteria predominate. Indeed, the former are seldom to be found in decomposing urine. This would appear to indicate the small comma bacilli to be *fermentative*, and the large straight bacilli putrefactive, organisms. And the fact that curved bacilli are found under varied circumstances in different regions of the mucous tract, surely points to the probability of their performing a certain set normal piece of work in the animal economy. In urine we have seen that their life history is closely associated with the pre-putrefactive or fermentative state of the change which this excretion undergoes. Now, we either know or suspect that fermentation plays a part in the digestion which takes place in the lower portion of the small intestine; but hitherto we have failed clearly to identify the agency by which it is accomplished. And here, I think, some light has been shed by Dr. Koch's observation that growing colonies of comma bacilli liquefied in their immediate neighbourhood the proteids on which they grew. We have it on good authority that the bacillus butyricus is commonly found in the stomach and intestine of herbivora, and the fact that this organism has the property of decomposing cellulose at once explains its importance in the digestive process of such animals. Why, then, should a similar zymogenic function not be attributed to an organism like the comma-shaped bacillus, which seems to have its normal habitat in the presence of mucous membrane in the human body? Indeed, I should not be surprised to find it conclusively proved that the comma-shaped bacillus is specially concerned in nitrogenous fermentation. Dr. Koch has drawn much more momentous inferences from arguments of a not less speculative character, and that, too, in the face of experiments, the negative result of which went to disprove his own hypothesis; and if I say that a superabundance of comma-shaped bacilli is found in the small intestines of cholera victims, because it would appear that whatever gives rise to that ailment brings about exalted fermentation in that part of the alimentary canal, I shall, at least, have as much logic in my assertion as he had in declaring that these organisms must bear a causal relation to the disease.

I am, Sir, yours, &c.,

GEORGE WATERS,
Surgeon-Major, I.M.D., Professor of Pathology,
Bombay, Oct. 17th, 1884. Grant Medical College.

COCAINE FUNGUS.

To the Editor of THE LANCET.

SIR, I feel it is my duty to point out to those who are using cocaine largely, either in ophthalmic or vesico-urethral practice, a danger which I have reason to suspect lurks in stale solutions of the alkaloid. A peculiar mould growth soon appears in the weaker solutions (4 per cent.), and apparently possesses the power of setting up inflammation of the mucous membrane to which it has been applied. It is well known that the epithelium is denuded by the action of the drug. The facility thus afforded to rapid absorption, or to direct action upon the tissues of any deleterious matter, is unquestionably great. Much greater, then, is the risk of absorption in operative procedure when cocaine is employed e.g., iridectomy, lithotrity, internal urethrotomy, &c., for here division or laceration of the tissues coexists with epithelium denudation. The most scrupulous asepsis of our solutions, as well as of instruments, is therefore imperatively demanded. My attention was first drawn to the subject by a stricture patient, whom I had treated with cocaine, complaining of profuse urethritis. As I had previously used the same solution with marked success in over fifty cases of stricture in urethral neuroses, lithotrity, &c., I could not account for the discharge, and was inclined to blame the patient sooner than damage the infant but brilliant reputation of the alkaloid. Two more stricture patients, however, appeared, both having been treated with cocaine, each of whom returned with acute urethritis (one with chordee). I examined my 4 per cent. solution, and found the mould growth I mention. Since my solution has been changed no fresh complication has occurred. I believe the stronger solutions do not permit the growth of the fungus, for with a 20 per cent. solution made on the same day as the one at fault I partially removed a large laryngeal papilloma without any resulting inconvenience, and on examination yesterday no fungus could be seen in it. Although the microscopical report of the growth is not yet to hand, nor am I able to adduce additional or more certain proof that the fungus *per se* has the power of setting up inflammation, I do not hesitate to publish the above facts, and trust their recognition may prevent other similar and more serious mishaps.

I am, Sir, yours truly,

HURRY FENWICK.

George-street, Hanover-square, W., Jan. 26th, 1885.

MEDICAL OFFICERS OF HEALTH AND PRIVATE PRACTICE.

To the Editor of THE LANCET.

SIR, The subject of your leader of last week is one in which I have long taken interest, and I therefore ask permission to say a few words thereon.

While agreeing generally with the views you express, I would point out that after twelve years' experience of the working of the Public Health Act, the number of towns or districts in which the state of public opinion is such, at the present time, as to enable the authority to guarantee a salary sufficient for the payment of the entire services of a competent officer of health is very few indeed. Such a salary ought not to be less than £600 per annum (seeing that there is no pension attached to the office); while in the case of a tried and valued officer, who has devoted his whole time and energies during some of the best years of his life to the public medical service, and who is precluded from otherwise adding to his income, the sum of £800 might fairly be considered as reasonable remuneration. But, excepting Glasgow, Liverpool, and Birmingham, there is no town where public opinion is sufficiently advanced for this, and in those mentioned the salaries given are much below that which should be accorded to the principal medical adviser of the corporate authorities of those great cities. In another twelve years things may

be changed, but at present I am strongly of opinion that entire exclusion from private practice ought not to be thought of in towns of less than a quarter of a million of inhabitants. Meanwhile, I think it is most unwise to encourage the idea that exclusion from practice is essential for the proper and conscientious performance of the duties of a medical officer of health. Some of the most highly cultivated and capable men, of good standing in our profession and in the towns where they reside, are, manifestly to the public disadvantage, thereby excluded from a branch of the public service in which the power of scientific observation, professional knowledge, tact, and influence are urgently needed. I am tempted to refer to a case in point - that of Cheltenham, a place with only 40,000 inhabitants, the health officership of which town is now being advertised at £300 per annum. Can it be possible that the authorities have been so unwise as to prohibit candidates who are engaged in private practice, while there is a physician residing there who has already done valuable work in the field of preventive medicine, and who would be willing to perform the duties of the office for the sum named?

You refer in your article to the fact that "some medical men, in their desire to get a footing in the sanitary service of the country, have undertaken to give themselves wholly to sanitary work at salaries which they should have regarded as hardly ample to command their services for more than one or two days a week." I regret to say this is perfectly true, as I know from my own experience during the past year. You do not, however, refer to what is still more to be deplored for the sake of our profession - namely, that medical officers whose "whole time" has been secured for salaries which may be stopped at the will of a town council have suffered those badly advised public bodies to thrust upon them duties of a most unprofessional character. If I were to enumerate some of these your readers would be surprised and shocked. Indeed, nothing illustrates more remarkably the unwisdom of excluding medical officers of health from private practice in towns or districts where public opinion is not ripe for such exclusion to be insisted on with advantage to the public than what has taken place of late in some of the northern towns of England.

I am, Sir, yours truly,

EDWARD SEATON, M.D.

George-street, Hanover-square, Jan. 27th, 1885.

To the Editor of THE LANCET.

SIR,—Your leading article in the last issue is an able and impartial analysis of conditions affecting medical officers of health, and deserves the thanks of all concerned; but still it seems to me that the circumstances are so involved in an atmosphere of neutral tint as to leave the object itself still obscured. As regards private practice (implying *ceteris paribus*), I believe it to be the opinion of a large number of practitioners themselves that it would in many ways cripple the independence of action in regard to public duties, and I know the appointment to have been declined for this reason alone. Again, with increasing private practice, how far can such increase extend without unduly encroaching on public duties? or could there be any proviso as to the number of hours daily or weekly to be devoted to the latter?

Now, Sir, there is a large section of medical men whose claims you omit to notice altogether, but whose special training and experience admirably adapt them for these appointments. I mean retired or half-pay medical officers of Her Majesty's army, superannuated too late in life (fifty-five) to commence the long struggle for success in private practice, but possessing valuable experience in all matters of sanitation; meeting and dealing as they have been accustomed to do with large bodies of men, women, and children directly, on their own responsibity, under all and varying circumstances, at home, abroad, in peace or warfare. From this point of view I might ask, Where was hygiene first reduced to, and taught as, a science in England if not at the Victoria Hospital, by Dr. Parkes, its founder, I might almost say its inventor, whose mantle fell upon a school regarding him with admiration and esteem; and thence diffused by his great work on the subject, a complete and crystallised gospel of hygiene? His genius, in my opinion, has scarcely received the recognition he deserved, though his book contains not only almost all that is as yet known on the subject, but also (preface) sentiments as profound and eloquent as any in our language. Again, I might point to the connexion between phthisis pulmonalis and defective ventilation, brought to light by the Army Sanitary Commission of, I think, 1858, in consequence of the reports and statistical observation of medical officers. I might adduce further examples, but I think I have said enough to show how important a factor sanitation is in the duty of the army medical officer, while at the same time there are numbers of unemployed active officers sufficient to form a corps d'élite for such service. It even appears to me the Director-General might arouse himself and point out to Government that it owes some *amende* (which might be made on these lines) to many officers whose promotion and prospects have been ruined by an *ex post facto* enactment.

I am, Sir, your obedient servant,

Jan. 27th, 1885. H. D. F.

THE EXTINCTION OF CHOLERA EPIDEMICS IN FORT WILLIAM.

To the Editor of THE LANCET.

SIR,—The letters of Drs. Marston and Mouat on the above subject call for a few remarks from me. In the first place, I must express my satisfaction at being supported by these distinguished officers in asking for an exhaustive inquiry in this case. Dr. Marston contends that the cessation of the epidemics should not be ascribed to the change made in the water-supply in 1865, for three reasons: (1) That long prior to the change—viz., between 1831 and 1837 - the cholera mortality was almost as low as it has been since; (2) that during the ten years ending in 1879 there has been a marked decline in the cholera mortality in Northern India, and he implies that the decrease in Fort William was only a part of this general decrease; (3) that many other sanitary improvements were made in Fort William to which the cessation of the epidemics might be as much due as to the change in the water-supply. I shall deal with these objections *seriatim*. With regard to the first point, there is reason to believe that Dr. Marston has been misled by imperfect returns. As there was no hospital in Fort William, the sick were treated at the Presidency Hospital, about a mile from the fort; and I find that in the years referred to eighty-three British soldiers, most of whom, *it is almost certain*, belonged to the Fort William garrison, died in the institution. Dr. Marston does not allow for these deaths; and the figures he quotes probably refer only to deaths that occurred so suddenly that the patients could not be removed to hospital. With regard to the second objection, it would be easy to show that the decrease of mortality for cholera in Northern India was due not so much to a decline of epidemic influence as to the withdrawal of a large proportion of the troops to the hill stations, where the risks of infection are comparatively small. The proportion of the troops in the hills having increased from 12 to 26 per cent. of strength, it is not to be wondered at that the cholera mortality fell from 9·24 to 4·18 per 1000. With regard to the third objection, I am glad that Dr. Mouat has stated the recommendations that were made by his committee in 1858. I conclude from Dr. James Anderson's description of the drainage and other sanitary arrangements in 1860 that the recommendations made had all been carried into effect by that time, except those relating to the water-supply. When I examined the fort in 1876 the drainage and conservancy arrangements exactly corresponded with Dr. Anderson's description. But although that able officer described "the barracks and fort altogether as kept remarkably clean," the garrison suffered heavily from cholera in 1860, 1861, and 1862. In the first of these years there were no fewer than 59 cases amongst the British troops. These facts seem to me to compel the conclusion that the change made in the water-supply was the main cause of the cessation of the epidemics. The health statistics of Fort William since that reform present a remarkable contrast to those of the principal stations of Northern India from the same period. The average death-rate of Fort William for the last eighteen years, for which statistics are available, was 12·3; that of the other principal stations 23·7 per 1000.

I am, Sir, yours truly,

Bray, Jan. 28th, 1885. A. C. C. DE RENZY.

THE USE OF COCAINE IN MINOR SURGERY.

To the Editor of THE LANCET.

SIR,—The following is, I think, a good instance of the value of cocaine in small operations:—

Miss B——, whose breast I removed for scirrhus in February, 1884, found a week ago that two small nodules of the disease, each about the size of a pea, very hard and painful, had appeared near the cicatrix of the operation wound. The nodules were about three inches apart. On January 23rd I injected three minims of a 4 per cent. solution of the hydrochlorate of cocaine on either side of one nodule; and, finding that after waiting ten minutes there was no pain on pinching the part, I cut down and removed the nodule, having to make an incision an inch and a half long. The patient felt absolutely nothing of the operation until I inserted the sutures, and that, she said, was hardly to be called pain. After closing the wound I injected another three minims near the second nodule, and operated in the same way; and although a little pain was felt, owing, I believe, to my not having waited sufficiently long for the third injection to take effect, it was very trifling; and from beginning to end this operation under cocaine was a decided success. There were no after-effects from the drug, and both wounds are healing by first intention.

I am, Sir, faithfully yours,

J. HERBERT SIMPSON, M.D.,
Surgeon to St. Cross Hospital, Rugby.

THE ADMINISTRATION OF ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—Being deeply interested in the administration of anæsthetics, I have read in this day's LANCET an account given of a death during or apparently subsequent to the administration of ether in the London Hospital on the 14th instant, reported by the house-surgeon, Mr. Proctor Selby Hutchinson. From a careful perusal of the same I have come to the conclusion that ether should not be blamed for the unhappy termination in the case. The post-mortem examination, independent of the anæsthetic used, revealed causes quite sufficient to produce death—viz., "The lungs were found emphysematous and congested. There was bronchitis, with a quantity of mucus in the tubes. The lower lobes did not contain much air. At the upper part there was more œdema. Trachea congested, containing frothy secretion. Heart flaccid, right ventricle and auricle occupied by soft coagulum; great increase of fat on surface of the same, and very little muscular tissue." Mr. Hutchinson states that Dr. Turner, who made the autopsy, considered that death had been brought about by fatty heart combined with bronchitis and emphysema; an opinion with which I cordially agree.

What I now wish to state is what I have stated repeatedly, and that is that all anæsthetics are dangerous, and will induce death if pushed too far; but of all anæsthetics I believe ether, properly and judiciously administered, is the safest, for it will never produce syncope or failure of the heart's action, no matter how much is given. It will produce asphyxia, or failure of respiratory action; but, as this is a very slow process compared to the former, timely warning is given to the anæsthetist to anticipate and prevent any untoward result, whereas syncope comes on and ends with such rapidity that there is no time for remedies. I also maintain that when bronchitis or pleuro-pneumonia is present to any great extent, ether or any anæsthetic is dangerous to use, and should not be administered.

In the administration of such agents I would suggest 1. That all anæsthetists should understand the properties and dangerous effects of each anæsthetic administered. 2. That all administrators should be qualified physicians or surgeons, and that they should carefully and thoroughly understand the process and degrees of anæsthesia before undertaking the very grave duty and responsibility of placing a human being into the mysterious sleep of insensibility. 3. That previous to any anæsthetic being administered, a careful and thorough examination of the thoracic cavity and its contents should be made, so as to detect, before it is too late, bronchitis or other pulmonary affection, as well as the condition of the heart. 4. That the administration of ether or any other anæsthetic should not be prolonged beyond the actual time required for the performance of the surgical operation. This I think it right to mention, as in a recent visit to some London hospitals I observed that the administration of ether with my inhaler was continued long after, in my opinion, there was any necessity for its use. After the main steps of an operation are over, anæsthesia, in the majority of cases, need not be continued. 5. At the slightest approach of danger, such as lividity and pallor of the face, stertorous breathing, cessation of the respiratory action or pulse, the anæsthetic should be at once discontinued, and fresh air given to the patient; and even when he has come round, the anæsthetic should not be there and then again administered, even should it be necessary to postpone the operation. The continuance of an anæsthetic after such warning symptoms can only lead to the most unfavourable consequences. 6. That the person deputed to administer the anæsthetic should devote his entire attention to the anæsthesia of the patient and to nothing else. He should not attempt to look about him or observe the progress of the operation. When mishaps have occurred they have frequently been due to inattention on the part of the anæsthetist. A competent and careful anæsthetist is, in my opinion, as important, and vested with as much responsibility during an operation, as the operator himself.

I am, Sir, yours truly,

L. HEPENSTAL ORMSBY, M.D., F.R.C.S.,
Surgeon to the Meath Hospital and County Dublin Infirmary.
Merrion-square West, Dublin, Jan. 24th, 1885.

WHOLE-MEAL BREAD.

To the Editor of THE LANCET.

SIR,—In some remarks upon wheat-meal bread in a recent number of THE LANCET, you mention me as the author of important improvements in the decortication of wheat; whereas, in fact, I am opposed to the decorticating treatment, because it fails to accomplish the object intended. My improvements comprise a new and original system of meals and breads which not only raises the standard of the products, but saves their cost and facilitates their manufacture. That is, having been at work practically upon the subject ever since originating the granular meal, and giving the process for it to the Bread Reform League, there has been built up by me, and step by step, a series of processes which will yield breads of superior excellence at the minimum of cost.

Yours truly,

CAMPBELL MORFIT.

Alexandra-road, Abbey-road, N.W., Jan. 22nd, 1885.

*** Dr. Campbell Morfit has forwarded to us three loaves of bread, illustrating his process and representing bread of the non-ferment class. No. 1 represents all the farina of wheat with some cerealine, amounting to 82-84 per cent. of the grain. No. 2 represents 94 per cent. of the wheat grain, or all except the tough portion of bran. No. 3 represents coarsely-ground wheat without any deduction whatever.—ED. L.

THE PRESERVATION OF THE DEAD IN MORTUARIES AND ELSEWHERE.

To the Editor of THE LANCET.

SIR,—The arrest of decomposition in the dead is a matter the importance of which forced itself urgently upon my consideration during the heat of last summer in the execution of my duties as a coroner. The Local Government Board have issued suggestions and plans for mortuaries, which are very excellent if only the sanitary authorities would follow them; but at present, in some large and important districts, no public mortuary exists; and in others where there is one the best means are not taken of preserving the bodies from decomposition, nor are there even proper arrangements made for making a post-mortem examination. But my present communication is to beg the use of your columns in order to throw out a suggestion, having for its object the arresting of decomposition in bodies by means of cold.

I would suggest that in all mortuaries, where possible, there should be made a case of iron, enamelled or galvanised, sufficiently large to hold four, six, or eight bodies, divided into compartments of about 7 ft. long, 2 ft. wide, and 2 ft.

high, by slides of the same material, surrounded by outer casing, also of the same, about 6 in. larger at the sides and back, covered with a jacket of felt and wood about 2 in. thick combined, to prevent conduction of heat. This outer space is for the reception of a mixture of salt and broken ice. The top should be closed by a lid, hinged in order to put in fresh ice and salt, and a tap should be made at the bottom to let out the meltings. There should be a door of iron covered with felt and wood, but it would not require any double casing for ice. The top would be as the door. Such a case to hold six bodies would occupy a space of about 7 ft. 9 in. long, 5 ft. 4 in. wide, and 6 ft. 2 in. high. Ice cases to hold a single body could be constructed on the same principle. When a body was required for examination or for any other purpose, a table capable of elevation could be placed before the open door and the shelf run out upon it. In many positions where steam or gas power could be used an ice-making machine could be employed instead of ice. It would be easy to make arrangements at the door end of the shelves, so as to give absolute security against any interference with the bodies within.

Cold, it appears to me, offers better advantages over other methods of preservation, leaving as it does the body completely intact. But by whatever means conservation may be effected its advantages are at once recognised as embracing the following points.

1. The prevention of disagreeable or dangerous odours. This is especially necessary where the mortuary is situated near houses or in hospitals; an instance of this latter has come under my notice where the mortuary is placed in the basement of the wards. In summer the effluvium finds its way into the windows of the wards; consequently, when an inquest is to be held urgent messages are sent to get the inquiry over directly, which is often impossible.

2. The coroner's inquest need not be unduly hurried, and this is of much importance in populous districts, both from the many engagements of the coroner, but also that it enables the jurymen to receive fair notice, so that they may arrange their own business accordingly, and gives time for the collection of evidence, thus preventing the necessity of adjournments.

3. In regard to identification, it gives greater and more complete facilities for the recognising of the dead. It will be at once seen how important this is from a legal and social point of view. Hitherto a week only is possible for identifying a dead body, and not unfrequently only a day or two. But by the plan suggested there would be no limit of time; and I see no reason why, in cases where the body has not been identified at the time of inquest, it might not be removed from the local to a central mortuary, and thus preserved for a period—say, a year. Portions of bodies like those lately found may in like manner be placed and kept until all means of inquiry concerning them should be exhausted, or may not the body of one dying far from his friends be preserved until arrangements can be made for burial or for a last look?

I am, Sir, yours truly,

A. BRAXTON HICKS,
Barrister-at-Law and Deputy-Coroner for Westminster and Surrey.

January, 1885.

THE M.D. EXAMINATION AT LONDON UNIVERSITY.

To the Editor of THE LANCET.

SIR,—We have read with surprise and a certain degree of amusement the views of your correspondent who signs himself "M.B.," relating to the "undignified complaint of one who aspires to a good degree." He evidently regards the passing of examinations as a much higher test of a man's capabilities as a practical physician than do we, who must confess a certain leaning towards the "schoolboy view" of your former correspondent. Moreover, "M.B." probably possesses a greater faculty for remembering the various facts and minutiæ which are necessary to ensure success in an examination like that for the London degree than is possessed by the majority. On these grounds we can respect his views. But when your anonymous correspondent turns aside and begins casting a slur on the teachers of practical medicine at the various London hospitals, contending "that he can count these teachers of clinical medicine on the fingers of one hand," we must confess to taking exception at his statement. The most obvious deduction that can be drawn from this remark is that either "M.B." has been endowed with an exceptional number of fingers, or that he has been singularly unfortunate in his experience. As we form two out of the remaining five who had the misfortune to be rejected in logic and psychology, though passing in medicine, we think that a disclaimer is not uncalled for.

We are, Sir, yours faithfully,

WALTER HULL.
F. FOORD CAIGER.

St. Thomas's Hospital, January, 1885.

THE CASE OF DR. BRADLEY.

To the Editor of THE LANCET.

SIR,—In last week's issue I am said to have given it as my opinion that an epileptic fit would not be recovered from in less than half an hour. That such a statement was made by me either in or out of Court I most emphatically deny. On the Sunday following the alleged offence I had an interview with Dr. Bradley. I asked him what kind of a fit it was that Mrs. Swetmore had, as her mother and friends had told me that her attacks usually lasted upwards of half an hour. He said it was a fainting fit. On this point I should almost feel disposed to differ from him; for if, as he alleges, she had a fit, it would probably be one of an epileptoid character. The learned counsel for the defence did not dwell upon the probabilities of women of a neurotic taint (of which Mrs. Swetmore is a type) suffering from delusions. In fact, I do not remember being asked a single question on this very important subject. That Dr. Bradley did not take my advice and obtain a professional expert as a witness is equally as much regretted by me as yourself; but that he had an "independent witness," and one who sympathised with him in his terrible calamity, you may rest assured.

I am, Sir, yours truly,

AMBROSE M. PALMER, M.R.C.S., &c.

Whittington, Jan. 27th, 1885.

LIVERPOOL.

(*From our own Correspondent.*)

HOSPITAL SUNDAY AND SATURDAY.

THE amount collected on Hospital Sunday has, as was feared, fallen short of previous years, owing to the inclement weather which prevailed, and also to the great depression of trade. It is hoped, however, that the deficiency may be made up by the improvement in the Hospital Saturday Fund, strenuous efforts being made to make this more generally known among working men, and to ensure more generous support. At the various annual meetings of the different medical charities which are now being held, the support received from Hospital Sunday is warmly acknowledged, and indeed is regarded as indispensable.

THE HOSPITAL FOR WOMEN.

The annual meeting of the Hospital for Women was held on the 26th inst., when the medical report read by Dr. Burton showed that the patients came not only from the city and neighbourdood, but from all parts of Lancashire, from Cheshire, North Wales, the Isle of Man, and elsewhere. The following was given as the summary of the year's work:—The number of patients treated at the dispensary department was 3397, with an attendance of 14,375. The in-patients numbered 363, with a mortality of 18, which is small considering the dangerous nature of many of the cases and that there were 249 operations. The expenditure was £1800, all of which had been raised, the hospital thus paying its way. £108 was received from fifty paying patients, while the dispensary patients' contributions amounted to £262.

THE INFIRMARY FOR CHILDREN.

At the annual meeting of the Infirmary for Children it was reported that the in-patients numbered 998 during the year 1884, while the out-patients were 12,234, and the daily attendances 30,779. In consequence of the depression of trade there was a deficiency of £323 on the income of the institution, which to that extent fell short of the expenditure. The following statistics respecting the mortality of children in this city was furnished to the committee by the medical officer of health:—Number of deaths under one

year, 3914; between one and two years, 1674; between two and five years, 1320; between five and ten years, 523; between ten and fifteen years, 239—total, 7670. The total number of deaths of all ages in the city for 1884 was 14,382. It will be at once apparent what a large proportion the mortality of infants and children bears to the total number, and that institutions whose object it is to reduce this mortality deserve support.

THE EYE AND EAR INFIRMARY.

Mr. Shadford Walker has resigned the office of surgeon to the Eye and Ear Infirmary, his term of office having expired. It would be impossible to give any idea of the extent to which the institution is indebted to Mr. Walker for his long and valuable services, first as assistant-surgeon, subsequently as surgeon. A greater contrast than the position of the infirmary as it was when he was first appointed to it and as it is now could hardly be imagined; and it is only justice to him to say that the change is largely due to his energy and influence. During the year 1884 the new eye cases numbered 7647, the new ear cases 2455; the former received 29,175 attendances, the latter 11,624. There were also 721 patients received into the infirmary as in-patients; the important operations performed among them numbering 460. The infirmary will still have Mr. Walker's services as consulting surgeon.

FEVER IN LIVERPOOL.

At the last meeting of the Health Committee it was stated that the following cases of infectious disease had been reported:—Fever 14, of which 11 were removed to hospital; small-pox 6, of which 5 were removed to hospital; scarlatina 38, of which 5 were removed to hospital. The report of the city hospital for small-pox cases was for the week ending Jan. 22nd as follows:—Remaining in hospital at date of last report, 23; admitted since, 11; discharged convalescent, 4; died, 1; remaining in hospital, 29.

Liverpool, Jan. 27th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

VOTE OF THANKS TO THE NEWCASTLE POLICE SURGEON.

AT the last meeting of the Council the subject of the resignation of Mr. S. W. Rayne came up for consideration, and in accepting that gentleman's resignation the Council tendered a unanimous vote of thanks to him for his services, during which there has not been a single case of complaint against him. Mr. Rayne has served the town as police-surgeon for the long period of forty years, during which he has seen more than one complete change in the Council. The vote was ordered to be engrossed on vellum. The committee at the same meeting recommended the election of Mr. Baumgartner to the vacant office.

LEAD-POISONING IN WORKPEOPLE AT GATESHEAD.

The subject of lead-poisoning, which has come into rather frequent prominence in our district of late, came before the Gateshead guardians last week. It appears that a girl employed at one of our large lead works had been ordered to the workhouse with symptoms of chronic lead-poisoning. The chairman said that a short while ago they had reported two other cases to the Local Government Board, but as these arose prior to the new Act coming into operation nothing could be done. The present case, however, would be one for the Local Government Board to deal with, and it was agreed to report it.

GERMS AND DISEASE.

Dr. McAlister of Cambridge recently lectured at Newcastle on the subject of "Germs and Disease." The lecturer, after glancing at the figurative use of the word "germ," and the old germ theory so-called, pointed out that the pathologist and disease investigator of the present day looked for the cause of disease or disorder of the body in some disturbing agency introduced from without. Their attention thus became fixed on the disturbing entity, whatever it might be. The influences might be analysed into three groups, than which it was hardly possible to conceive anything simpler—viz., mechanical, chemical, and thermal. There was another group of disturbing agents whose action was much more complex, and which had not yet been reduced to these simple classes or categories. He meant the parasites of the body. The human body sustained at all times an enormous number of parasites, both animal and vegetable. The animal were less harmful than the vegetable. Some of the plants, so to call them, did no harm; others had very slight and local effects; and others invaded the whole system, took it captive, and caused widespread mischief. It was to these last that the lecturer principally alluded by the term "germs," and he showed that our knowledge of these last had greatly extended during the last fifteen or twenty years, owing principally to the aid afforded by the microscope. He then propounded the question, In what way do these germs set up disease? and said we were on the border of the unknown, and in a region in which during the next hundred years probably great discoveries would be made. The lecturer next alluded to the known relation between plant or germ life and zymotic diseases, and said there was overwhelming evidence that the microphytes stood in relation of cause and effect to disease; what was required to raise it to a point of absolute certainty remained to be pointed out. In the class of zymotic diseases the chain of proof, though nearly closed, could not be positively connected, owing to the insusceptibility of the lower animals to inoculation; on this point no doubt clearer light would be shed in a few years. In conclusion, Dr. McAlister said one of the great objects of modern medicine was the aim to render the whole class of plants concerned in zymotic disease extinct. He was in favour of much more stringent laws as to isolation, notification, &c. The lecturer illustrated his subject very ably, and was listened to throughout with great attention.

Newcastle-on-Tyne, Jan. 21st.

SCOTLAND.

(From our own Correspondent.)

INVITATION TO THE BRITISH MEDICAL ASSOCIATION TO MEET IN GLASGOW.

THE discussion as to the advisability of inviting the above Association to meet in Glasgow at an early date has now ended in the declaration by the University authorities that they are willing to co-operate in sending such an invitation for the year 1888. As the Faculty of Physicians and Surgeons has also indicated a desire to co-operate in the same undertaking, it may be regarded as tolerably certain that in the above-mentioned year the Association will meet in this city.

HEREDITY IN CRIME.

Something very like heredity in crime was illustrated in a case which came before one of the Glasgow police-courts a few days ago. A boy of twelve years of age was found guilty of stealing a pot of marmalade from a cart in the street, and was sentenced to four years' detention on board a training ship. In the course of the evidence it came out that at present the boy's mother, grandmother, and uncle are in prison, while his father has deserted him.

ABERDEEN UNIVERSITY.

The Senatus of Aberdeen University have had under consideration the advisability of enlarging the university buildings, principally in connexion with the medical school, so as to adapt it to the growing demands on the present insufficient accommodation.

GLASGOW ROYAL INFIRMARY.

The most exciting event of the past week was the annual meeting of contributors to the funds of the Glasgow Royal Infirmary, at which the medical element in the management for once scored a distinct success. After a very satisfactory general and financial report had been considered and adopted, a question was raised for settlement which ought never to have gone before a lay jury at all namely, Is enteric fever infectious, and is it judicious to treat it in the wards of a general hospital alongside other patients, more especially when there exists in the city a special hospital for the reception of such cases? The chairman of the managing board, together with a few other lay directors, went dead against the expressed view of the entire staff and of the medical directors in the matter, and wished to follow what is described as the invariable practice of the infirmary for

ninety years, in treating such cases within the institution. On being defeated at the managing board, these lay directors determined to take the unprecedented step of bringing this strictly medical question before the general meeting of contributors, with the result, however, that the public have endorsed the very reasonable attitude taken up by the medical directors and staff—namely, that in future such cases should not be admitted for treatment in the wards of the Royal Infirmary, an institution in which the treatment of zymotic diseases was expressly given up some ten years ago.

IRELAND.

(From our own Correspondent.)

MR. RAWDON MACNAMARA has been re-elected representative of the Royal College of Surgeons in Ireland on the General Medical Council.

BRITISH MEDICAL ASSOCIATION.

The annual general meeting of the Dublin Branch of this Association takes place this week at the College of Physicians, when the President-elect will deliver an address, and the office bearers will be elected by ballot for the ensuing year. Notice has been given by Dr. C. F. Knight that he will move the following resolution: "That in the opinion of this meeting it is desirable that three or four meetings of this branch be held during the year for the discussion of matters of professional interest, in addition to the annual meeting, and that the incoming Council be requested to make the requisite arrangements." The annual dinner will take place in the evening in the College Hall.

AMPUTATION AT THE HIP.

This operation was performed on Tuesday last at the Adelaide Hospital, Dublin, by Mr. J. Kellock Barton. The patient, a girl about fifteen years of age, had undergone an operation for excision. Mr. Barton adopted Furneaux Jordan's modified operation of skin flaps, with circular incision, which has a good deal to recommend it, more particularly as regards the facility for securing the femoral. In this case the operation was rendered tedious and troublesome by the firm ankylosis which existed, and which obliged Mr. Barton to saw the bone across before completing the operation. Esmarch's bandage was used instead of Davy's lever. The operation was performed under strict antiseptic precautions.

MEATH HOSPITAL, DUBLIN.

The governors of this old and valuable institution have issued a special appeal for funds, and it is to be feared, should a favourable response not be forthcoming, that a portion of the wards will have to be closed, at all events for a time. The hospital account has been overdrawn by about £1400, but this sum and nearly £4000 of invested capital have been expended in carrying out certain improvements which were absolutely necessary. These include a disinfecting chamber, lavatories and dressing-rooms attached to the fever wards, and two observation wards for the reception of doubtful cases.

STEEVENS' HOSPITAL, DUBLIN.

An election for a resident surgeon, in the room of Mr. Myles, took place last week, when, of five candidates who competed, Mr. John Neill, of the Ledwich School of Medicine, was elected unanimously. The selection was a judicious one, as Mr. Neill is a very successful private teacher, and has earned golden opinions from all with whom he has come in contact during his professional career.

COUNTY KILDARE INFIRMARY.

At Naas Court-house last week a presentment for £600 for the maintenance of the county infirmary being taken up, a Poor-law guardian objected to the grant as a waste of public money, and said the majority of the cesspayers were opposed to it. On a division being taken, the motion recommending the grant was adopted by a narrow majority. I congratulate Dr. Chaplin, a gentleman of high professional attainments, who is the surgeon to the institution, on the result, and regard the opposition to the grant as most unjustifiable. County infirmaries throughout Ireland have done much good in the past, and their extinction would be a matter of regret to all unprejudiced persons.

Dublin, Jan. 27th.

PARIS.

(From our Paris Correspondent.)

THE SUSPECTED CASES OF POISONING BY COLCHICIN AND ARSENIC.

As mentioned in my letter of last week, the body of the woman who was supposed to have been poisoned by her husband with colchicin has been exhumed and taken to the Morgue for examination, together with three jars filled with the earth taken from around the coffin. The examination was performed by Professor Brouardel, assisted by Dr. Locquay, and in the presence of M. Ogier, a chemical expert. The report of Professor Brouardel (the details of which have not yet been published) having advised a chemical analysis of the viscera, these have been forwarded in sealed jars to the toxicological laboratory of the Prefecture of Police. A short time ago another case of suspected poisoning was brought to the notice of the judicial authorities, which occurred under circumstances almost similar to those mentioned in connexion with the florist referred to above. In this case, the supposed criminal, who is a clockmaker by trade, and also a dabbler in chemistry, is suspected of having poisoned his first wife with the view of taking a second. The examination was performed by Professor Brouardel and M. Lhotte, a chemical expert, the result of which was the discovery of undeniable traces of arsenic. M. Lhotte also analysed the earth from around the coffin by means of Marsh's apparatus, but no trace of the poison was found in it; neither was there any discovered in the mixtures usually employed by undertakers to preserve the body. The clockmaker is under close arrest on account of the strange disappearance of his servant, who is supposed to have been murdered by him and the body made away with, as no traces of her are to be found. He is kept in ignorance of his being suspected of having poisoned his wife, and of the proceedings that have taken place in connexion with it. He will be eventually examined on both these charges.

THERMOMETRIC RECORDS.

The weather just now is extremely cold in Paris, the thermometer having marked yesterday at 7 A.M. 23° F., at 11 A.M. 28·4°, and at 1 P.M. 32°. To-day it is rather inclined to thaw. In connexion with this subject, I may mention that the bulletin of the Paris Observatory notes that on October 25th last the coldest locality in Europe was found to be St. Maur, just outside Paris, where the thermometer registered 23°; it was the only observatory in Europe the thermometer of which stood below freezing point; whereas at Haparanda, on the Gulf of Bothnia, it marked nearly 25°. At Bodo the thermometer stood at 19·4°. At St. Petersburg and Moscow the temperature was four degrees higher than that at St. Maur. At Stornoway, in the north of Scotland, and in a great part of the northern regions, the thermometer registered 50°.

DRUGS FOR THE PARIS HOSPITALS.

The estimate of the quantity of medicines &c. required for the use of the patients in the Paris hospitals for the present year is as follows:—24,000 kilogrammes of liquorice root, 15,000 of cinchona, 80,000 of linseed, 6000 of mustard, 15,000 of cod-liver oil, 20,000 of glycerine, 3000 of orange-flower water, 250 of opium, 2000 of bromide of potassium, 50 of nitrate of silver, 500 of the subnitrate of bismuth, 60 of sulphate of quinine, 12,000 of carbolic acid, 10,000 of chloral. In addition to these drugs, the hospitals are annually supplied with 30,000 fresh lemons and 40,000 leeches. Fresh herbs are estimated to cost 1946 francs; dry herbs, 45,000 francs.

HEALTH OF VICTOR HUGO.

It was reported that Victor Hugo's health was in rather a precarious state. On inquiry I learned that the illustrious poet was merely suffering from an ordinary "cold," which, however, at his time of life, he being an octogenarian, would cause some anxiety, particularly as he had been seized by a troublesome cough. He is, I am glad to say, quite recovered, for he has resumed his usual occupations and his weekly receptions.

Paris, Jan. 27th.

ROME.

(From our own Correspondent.)

BRIGHT and bracing weather has succeeded the ten days' rainfall which swelled the Tiber into flood and inundated the lower quarters of the city; while snow lies deep on the Sabine uplands, and even Soracte stands out in the virgin vesture which inspired Horace, one memorable day, to the composition of a perfect ode. But for the usual tale of pulmonary affections, always more serious among the Italian than among the English speaking population, the health of the city is excellent, and all its characteristic attractions, recreations, amusements, only awaiting the votaries who seem so slow in coming. It is fair to mention, however, that within the last few days the arrivals have been many and distinguished, and before the month is out the season will have made a start as promising as the gayest of its predecessors.

The Commission on the Influence of Woods on the Malaria prevalent on the Roman Littoral has published its report, from which may be deduced the following conclusions:—1. The wooded parts of that region mostly remain what they were two centuries ago—namely, tracts of low brushwood, sometimes cultivated for fuel, never producing trees of any considerable stem. These tracts, moreover, are generally marshy. 2. The dogma, accepted for the last eighty years, that the clearing, whether total or partial, of these wooded tracts always occasions an increase of malaria is absolutely without foundation. Those places in which the wood had been destroyed were rather improved as regards malaria. 3. Without ignoring the benefit which well-reared woods confer on climate, the Commission, keeping within the sphere of its inquiry, has found no malarious district in the Roman province where the planting of trees has produced the slightest diminution in the force or extent of the fever. 4. The Commission can prove that the sensible augmentation of fever cases within the last few years in certain communes is solely due to the increased number of labourers brought to those places for special works, while in other communes the augmentation of such cases is traceable to the neglect or abandonment of hydraulic treatment of the surrounding soil, whether with regard to the atmospheric or underground waters, or with regard to those reserved for irrigation or special industries. The Commission is convinced that in certain places the neglect of sanitary precautions has tended greatly to intensify the effects of malaria. 5. The notable augmentation of fever in years like 1879, attributed by the population to the destruction or thinning of the woods, was found to have been common to the whole province, and in parts where no wood was touched. Medical statistics compared with those of meteorology demonstrate that these maxima in the number of fever cases throughout all the malarious districts are in direct relation with special meteoric facts. 6. Admitting the transport of the malarious germ by means of winds to no great distance, the Commission concedes that a country may derive benefit from an extensive and thick plantation well reared and interposed between the habitations and the malarious centre, provided the plantation as regards height, direction of prevalent winds, and distance, be so placed as to form a true barrier between the population and the malarious centre aforesaid. And yet in support of this opinion there is only the assertion that the new or low part of Terracina experienced an augmentation of fever after the felling of a cork-wood, which presented many of the above-mentioned conditions for protecting the population from the malaria of the adjacent districts. Nevertheless, it must be noted that almost contemporaneously with the cutting down of the cork-wood, other changes occurred in the hydraulic conditions of the place, which must have proved equally disastrous, even had the cork-wood barrier existed. 7. In other localities, dense plantations, as at Sermoneta and Piperno, and woods extending far and wide around the district, not so placed, however, in point of height as to form a true barrier between the townships and the neighbouring malarious tract, neither have been, nor now are, of any avail in arresting the malarious influence from the tract in question. 8. The Commission found that soils without drainage, covered with woods or undergrowth and not cultivated, are themselves sources of malaria. Nothing but drying the soil will diminish the malaria, it being indifferent whether the wood be maintained so long as the soil is well cultivated. 9. Although the Roman province is almost destitute of woods properly so-called along the littoral, the pine forest of Castel Fusano in the delta of the Tiber being almost the only one worth mentioning, still the Commission did not fail to test the argument based on littoral plantation. It cannot admit, with some authorities, that such woods can arrest the noxious vapour carried by the winds across the Mediterranean from remote regions, since, even were such vapours and such transport demonstrated, the woods could keep them off only a restricted zone of land immediately adjoining. The Commission, however, does not ignore the fact that important economic and agrarian interests prescribe the planting of the littoral. In this case not only the soil on which it is proposed to plant, but that which is in immediate contact with it, should be placed in such conditions that the waters may readily be drained off it; if not, there would simply be a new source of malaria.

The *Archives Italiennes de Biologie* contain two notable contributions by Dr. Tommasi Crudeli, one on the Malaria Epidemic at the Tre Fontane near Rome in 1882, and the other on the Discovery of the Cholera Bacillus. The former of these papers has in substance already been touched upon in THE LANCET (*vide* the numbers for November 1st and November 8th, 1884), while the latter may now be referred to as an elaborate revindication of Pacini's claims to having first opened up the track which has since been so keenly followed up. It was in 1854, in the *Gazzetta Medica Italiana* of Florence, that the Tuscan pathologist described the *microbio colerigeno* (cholera-producing microbe) as first seen by him in that year; and in 1855, and again from 1865 to 1867, he continued his researches, which by that time had attracted in Germany, France, and Belgium an attention denied to them in his own country. Dr. Tommasi-Crudeli, as Pacini's pupil, had occasion to test the doctrine of the parasitic origin of cholera at Palermo in 1866, when 4000 persons succumbed to the disease, and he deduced from his experience many practical rules which have since proved of the highest service.

Dr. J. G. Van Marter of this city has discovered at Corneto, near Cività Vecchia, two specimens of ancient dentistry as practised by the Etruscans, the tombs in which they were found dating from the fifth century before the Christian era. Dr. Van Marter describes this treasure-trove as the "earliest known essay in dental bridge-work," and is at present prosecuting his researches into the practice of stopping the teeth, of which indications have already been noted in prehistoric tombs. An interesting paper on the subject has already been contributed by him to the *Independent Practitioner* of New York.

Your contemporary, the *Gazzetta Medica di Roma*, founded and edited by the Cavaliere Dr. Filippo Cerasi, after ten years' vigorous life in a quarto form, now appears in the more convenient octavo size. The first number of the new series, which is published fortnightly, contains, besides much interesting matter, an able contribution by Dr. Torquato Baldelli on "Multiple Echinococcus of the Right Kidney."

Rome, Jan. 24th.

THE SERVICES.

Deputy Surgeon-General David Boyes Smith, of the Bengal Medical Department, has been appointed Professor of Military Medicine at the Army Medical School at Netley.

WAR OFFICE.—Artillery Volunteer Corps (1st Kent): John Irvine Boswell, Gent., to be Acting Surgeon.

INDIA OFFICE.—The Queen has approved of the following promotion among the officers of the Staff Corps and Indian Military Forces made by the Governments in India: Brigade Surgeon George Bidie, C.I.E., of the Madras Medical Establishment, to be Deputy Surgeon-General.

ADMIRALTY.—The following appointments have been made:—Surgeon W. W. Jacobs, additional, to the *Duncan:* Surgeon Samuel W. Vasey, to Malta Hospital: Surgeon Alfred Patterson, to Haslar Hospital; William Rowlands to be Surgeon and Agent at Waterloo.

RIFLE VOLUNTEERS. 5th (Deeside Highland) Volunteer Battalion, the Gordon Highlanders: John Hector Anderson, Gent., M.B., to be Acting Surgeon.—1st Lancashire: Acting Surgeon James Bruce Macpherson resigns his appointment. 1st Surrey (South London): Samuel George Milner, Gent., to be Acting Surgeon.

ROYAL COLLEGE OF PHYSICIANS.

AT the ordinary Comitia of Fellows on the 29th instant, Sir W. Jenner, Bart., President, in the chair, Drs. Fincham, Andrew, Hughlings Jackson, Reginald Thompson, and Broadbent were elected Councillors. The following gentlemen were elected additional Examiners in accordance with the Scheme for an Examining Board for England:—Chemistry: *Dr. Russell.* Materia Medica: Drs. F. Taylor and Murrell. Elementary Physiology: Drs. Ewart and V. D. Harris. Physiology: Dr. Pye-Smith. Medicine: Drs. Beale, Cayley, Moxon, Green, and Sutton.

The annual report of the Examiners was presented, from which it appears that during last year 782 candidates presented themselves for the first examination, 110 for the second, and 290 for the final examination for the Licence of the College; the percentage rate of rejections at each examination respectively being 35·4, 66·3, and 33·3.

The replies of the Committee of Management to the questions submitted by the Medical Council were adopted by the College. The most important was the opinion that two years was not a sufficiently long period for study of the subjects of the second division of studies.

On the motion of the Registrar, the College resolved: "That every member of an English university who shall have passed such an examination or examinations at his university as shall comprise the subjects of the first and second examinations of the Examining Board in England, and who shall have completed not less than four years of medical study according to the regulations required by his university, be eligible for admission to the third or final examination of the Board, two years after his having passed all the other required examinations; that every candidate so admitted to examination be required to pay a fee of five guineas; and that every such candidate who shall have passed such third or final examination shall, on the further payment of not less than twenty-five guineas, and subject to the Bye-laws of each College, be entitled to receive the Licence of the Royal College of Physicians of London, and the Diploma of Member of the Royal College of Surgeons of England."

The proposition was supported by several Fellows, including Sir H. Acland and Dr. Burdon Sanderson, who stated that the University of Oxford would probably accept the examination of the two Colleges as qualifying for its degree, provided that its graduates showed evidence of better attainments in scientific medicine. It was pointed out by Dr. Duckworth that the proposal included *all* the universities in England; and on his motion, a letter from the University of Edinburgh, claiming an extension of the same privileges, was referred to the Committee of Management.

The following resolution, which will enable candidates for the L.R.C.P. who began their course before October, 1884, to avail themselves of the new regulations, was also passed:—"That any candidate for the Licence of this College only examined after October 1st, 1884, may avail himself of the regulations relating to the examinations of the Examining Board in England."

The College then proceeded to some resolutions, moved by Sir W. Gull, bearing upon the present mode of election to the Fellowship; but, after a short discussion, the "previous question" was moved and carried.

MAHOMED MEMORIAL FUND.

Obituary.

DANIEL NOBLE, M.A., M.D., M.R.C.S.

DANIEL NOBLE, whose death occurred at Manchester on the 12th inst., was born at Preston in 1810. He received his medical education at the Borough School and Guy's Hospital; and after becoming a Member of the Royal College of Surgeons and a Licentiate of the Society of Apothecaries, he commenced practice in Manchester in 1834. In 1853 he received the diploma of M.D. from the University of St. Andrews, and in 1860 the honorary degree of M.A. was conferred upon him by the same university. In 1847, when Manchester was visited by an alarming and disastrous epidemic of typhus fever, Dr. Noble was the general superintendent of the extensive arrangements which were made for checking the progress of the disease; and in 1866, when a general apprehension prevailed, fortunately not realised, of a renewed visitation of cholera, his advice was again sought. In 1859 Dr. Noble was offered by the Chancellor of the Duchy of Lancaster an appointment as County Magistrate, an honour which he, however, declined. In 1867 he was elected a Fellow of the Royal College of Physicians. Among other works he was the author of the following: "Influence of Manufactures upon Health and Life," "The Brain and its Physiology," "Elements of Psychological Medicine," "The Human Mind in its Relations with the Brain and Nervous System." He also contributed a number of papers to various medical journals, amongst which may be mentioned: "Mesmerism True—Mesmerism False," "The Epidemic Fever of 1847," "Cerebro-Spinal Concussion, with illustrative cases," &c.

DERRY JONES, M.R.C.S., L.R.C.P.ED.

IN the death of Mr. Derry Jones, Islington has lost one of its representative medical practitioners. During the fifteen years he pursued his calling in this district he succeeded in building up an extensive practice, and also in drawing round him a large circle of friends. Mr. Jones was essentially a good fellow. His good looks, his vivacity, and his manner of story-telling—and few could tell a racy story with greater zest and artistic finish than Mr. Jones—all combined to make his company welcome. Among the students of University College, where he received his medical education, he was a great favourite. Though not a brilliant student, he took his share of prizes and medals, and he carried with him into practice the respect and good wishes of his teachers. His qualifications were M.R.C.S. & L.S.A., 1869, and L.R.C.P. Edin., 1876. In the art of getting on in practice Mr. Jones might well be taken as a model. Withal he was essentially a man of the world. He enjoyed life and the goodwill of his neighbouring practitioners. His patients trusted him; many loved him. He leaves as his chief mourner and only relative, strange to say, an aged mother, whom—and we would note it as chief among his social graces—he loved and tended with a jealous care. The kidney mischief which carried him off was quite unsuspected; and, indeed, his death must come as a surprise to all who knew him. Mr. Jones died on the 21st inst., at the age of forty-one years.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 22nd inst.:—

Ensor, Henry Collen, L.S.A., Llanishen, near Cardiff.
Eskrigge, R. Bertram, L.R.C.P. Edin., Hardwick, Manchester.
Sydenham, George Francis, L.S.A., Tiverton.
Bell, William Howard, L.S.A., Myddelton-square.
Malden, Frank James, M.B. Durh., St. Neots.
Newbolt, George Palmerston, M.B. Durh., Weymouth.
Davison, John Lorenzo, M.D. Toronto, Toronto.
Broadbent, George Harry, L.K.Q.C.P.I., Manchester.
Williams, Campbell, Sydney, New South Wales.
Leech, Priestley, L.S.A., Warrington.
Kershaw, John Cawthron, Ardsley.
Mann, John Bentley, L.K.Q.C.P.I., Manchester.
Aspinall, John, L.S.A., Hindley.

Admitted on the 23rd inst.:—

Robertson, Robert Smith, L.R.C.P. Ed., Manchester.
Jolliffe, Albert Robert, L.S.A., Southampton.
Leggatt, Gerald Stedman, L.S.A., Highbury-hill.
South, Henry Erskine, L.S.A., Balham.
Cree, Gerald, L.S.A., St. John's-park.
Adams, Gofton Gee, L.R.C.P. Lond., Clifton.
Ingle, Arnold Clarkson, L.S.A., Cambridge.
Anwyl, James Norman, L.S.A., Manchester.
Bower, Edward Ignatius, L.S.A., Craven-street.
Ballachey, Henry Holloway, L.R.C.P. Ed., Edgefield, Norfolk.
Langhorne, Thomas Grant, Holland-park-gardens.
Deeble, Stephen Lawson, L.S.A., Netley, near Southampton.
Chamberlain, Charles Basham d'Eyncourt, L.S.A., Southsea.
Priestley, Robert Chambers, L.S.A., Hertford-street.
Humphry, Ernest, L.S.A., Brighton.
Lovell, Harry Haynes, Barnstaple.
Mackay, William Bertie, M.D. Ed., Lancaster-road.

Admitted on the 26th inst.:—

Relton, Bernard, L.S.A., The Vicarage, Ealing.
Fetherstonhaugh, Robert Trevor, L.R.C.P.L., West Dulwich.
Hacking, John Herbert, L.R.C.P.L., Old Trafford, Manchester.
Pollard, Reginald, M.B. Durh., Torquay, Devon.
O'Brien, Patrick Moriarty, Liverpool.
Orr, Andrew Aylmer, Charlotte-street.
Little, Francis Ernest, Halsey-street.
Page, Harry Marmaduke, Westbourne-park.
Lewis, James King, L.S.A., Greenwich.
Napier, Francis Horatio, Lancaster Gate.
Mudge, Zachary Belling, Hale, Cornwall.
Windsor-Aubrey, Henry Wentworth, Hale, near Salisbury.
Harrison, Frank, Sheffield..

Admitted on the 27th inst.:—

Bowie, Robert Forbes, L.R.C.P. Lond., Forres, N.B.
Winckler, William Joseph, L.R.C.P. Lond., Ampthill-square.
Burn, Thomas William Barnett, West Brixton.
Flemming, Percy, Regent's-park-road.
Emmett, Richard, Clapham-common.
Goodall, Edwin, Portsdown-road.
Jones, Samuel Cromwell, Velindra, South Wales.
Hillier, Thomas Ernest, Cromwell Residences.
Reid, Edward Waymouth, Canterbury.
Haviland, George Darby, Hawkhurst.
Moody-Ward, Richard, St. Thomas's-street.
Laws, Cuthbert Umfreville, Newcastle-on-Tyne.
Wornum, George Porter, Belsize-square.
Cattell, George Trew, Brixton.
Roberts, Arthur, Bishop Stortford.

Admitted on the 28th inst.:—

Ackland, John McKno, L.D.S., Southernhay, Exeter.
Dundas, Mordaunt George, L.S.A., Forest Gate.
Wunderlick, Otto Frederick, L.R.C.P. Lond., Wallace-road.
Jones, Hugh Edward, St. Thomas's-terrace.
Heatherley, Francis, Newman-street.

[The name of Mr. Percy William Menzies, Bristol, who passed in Anatomy at the Primary Examination on the 8th instant, was inadvertently omitted from the list published last week].

COLLEGE LECTURES.—The annual course of lectures will be commenced on Monday, February 9th, at 4 o'clock, by Professor W. K. Parker, M.R.C.S.E., F.R.S., who will deliver six lectures on "Birds, their Genesis and Structure." Professor Frederick Treves, F.R.C.S., will deliver three lectures on "The Anatomy of the Peritoneum and Intestinal Canal in Man," commencing on Monday, February 23rd. Professor Charles Stewart, M.R.C.S., will deliver three lectures on "The Structure and Life-History of the Hydrozoa," commencing on Monday the 2nd March. Professor Alexander Hill, M.B., M.R.C.S., will deliver three lectures on "The Grey Masses of the Cerebro-spinal System, their relations to one another and to Peripheral Nerves," commencing on Monday, the 9th of March. Professor Arthur Brailey, M.D., M.R.C.S., will deliver three lectures on "Some Points in the Anatomy and Physiology of the Eye," commencing on Monday the 16th March. The course will be concluded in June next, by Professor Edward Lund, F.R.C.S., Professor John Wood, F.R.S., F.R.C.S., Professor Charles Stewart, M.R.C.S. (Erasmus Wilson Lecturer), and Edward Albert Schäfer, M.R.C.S., F.R.S., the subjects of the several lectures will be hereafter published. The lectures will be delivered in the theatre of the College on each Monday, Wednesday, and Friday, at 4 o'clock precisely.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 22nd inst.:—

Bluett, George Mallack, University College.
Bowman, Henry Claxton, Manchester Royal Infirmary.
Cox, Alfred Harold Lissant, King's College.
Cox, Joseph Bethel, St. Bartholomew's Hospital.
Cree, Gerald, Middlesex Hospital.
Earls, James Henry, Dublin.
Hallilay, Henry, Leeds School of Medicine.
Roach, George Ernest, Guy's and London Hospitals.
Scott, Joseph Sandbach, Manchester School of Medicine.
South, Henry Erskine, St. George's Hospital.
Taylor, John Francis, London Hospital.
Venis, Walter, King's College.
Watts, Henry Ernest, Westminster Hospital.

The following gentlemen also on the same day passed the Primary Professional Examination:—

W. H. Cundell, St. Mary's Hospital; W. A. Winships, Newcastle-on-Tyne College of Medicine.

At a meeting of the Court of Assistants of the Society, held on the 27th inst., the undermentioned gentlemen were by them appointed as Assessors in Surgery at the Hall:—George Henry Makins, F.R.C.S. Eng., Resident Assistant Surgeon to St. Thomas's Hospital; Wm. Johnson Walsham, F.R.C.S. Eng., Assistant Surgeon and Demonstrator of Practical Surgery at St. Bartholomew's Hospital, Surgeon to the Metropolitan Free Hospital.

H. B. GUPPY, M.B., R.N., H.M.S. "Lark," has been elected a Fellow of the Geological Society of London.

HOSPITAL SUNDAY in Sheffield, in aid of the medical charities of the town, realised over £2000, and it is expected that further returns will increase the amount.

ON the 27th inst., an inquest was held by Mr. George Collier at Bethnal-green on the body of a boy who, bitten by a dog on December 23rd, died from hydrophobia on the 23rd inst.

THE *Grahamstown Journal* of December 9th contains an article recommending Grasslands Sanatorium, situate about twenty-five miles from Grahamstown, as a place of resort for those in search of health and rest, and who require quiet, kindly attention, and a favourable climate.

CARDIFF MEDICAL SOCIETY.—The following gentlemen were elected officers for the ensuing year:—President: Charles E. Hardyman, F.R.C.S.E. Committee: C. T. Vachell, M.D.; A. P. Fiddian, M.B.; A. Plain, M.B.; W. Hier Evans. Secretary and Treasurer: Thomas Garrett Horder.

THE concert given by the employés of the London and North-Western Railway at Euston Station, in aid of the University College Hospital, has resulted in the appointment of a life governor and a life donor; £52 10s. having been paid to the secretary to the People's Constitution Fund.

ABOUT seventy names of persons desirous of joining the class at Dumfries in connexion with the Order of St. John of Jerusalem have been received, and fifteen ladies have entered for a ladies' class which is in course of formation. The former is conducted by Dr. Hunter Dryden, and the latter will be taught by Dr. Gilchrist.

THE Steam Yacht "Ceylon" sailed from Gravesend on the 24th, at 2.30 P.M., on her trip to Madeira, West Indies, and New Orleans, returning by way of the Azores. Among the passengers were Sir Francis and Lady Stapleton, Colonel the Hon. King-Harman, M.P., the Hon. Spencer Stanhope, General Trevor, Dr. Oscar Jennings, and others.

ON Tuesday, at South Hayling, Hants, Lady Fitzwygram, wife of Sir Frederick Fitzwygram, M.P. for South Hants, distributed certificates to the successful candidates in "First Aid to the Injured," a centre having been lately established at Hayling Island in connexion with the St. John Ambulance Association, and courses of instruction given by Mr. Percy Pope, M.R.C.S.

MANCHESTER AND SALFORD SANITARY ASSOCIATION.—At the annual meeting of this Association and its branches, held on the 27th inst., it was stated that the importance and influence of the Society and the amount of work accomplished were restricted by the scanty pecuniary support received from the public. Several reports recording the work done by the Association were read, and several resolutions of a purely routine character were passed, previous to the election of officers for the ensuing year, after which the meeting separated.

WESTMINSTER SANITARY AID ASSOCIATION.—The third annual meeting of this Society, of which the objects are to prevent the spread of infection, to show the poor how this is to be done, to assist them to carry out the necessary precautions, and to promote sanitary measures in general,

was held on the 27th inst. The report, which was read and adopted, showed that in the nine district parishes of Westminster the sanitary visitors of the Association had attended 233 cases within the past year, against 212 cases in 1883. There has been no epidemic in Westminster during the three years the Association has been in operation; and in no instance in which the visitors attended to a case of infectious disease did the illness spread to other inmates of the house. A small debt exists, to discharge which subscriptions are solicited.

AT a largely attended meeting of the Council of the Charity Organisation Society, on the 26th inst., the discussion upon the question of self-supporting dinners for the poor was resumed. It was finally resolved, by twenty-four votes to eleven, that the Council viewed with interest the experiments which were being made to give dinners to elementary school children, but were of opinion that in the interests of the poor themselves the dinners could and should be supplied on self-supporting principles, free dinners, or those at a merely nominal payment, having a tendency to pauperise the people, being clearly injurious.

WIRRALL CHILDREN'S HOSPITAL.—The annual meeting of the subscribers to this institution was held on the 19th inst., the president (Mr. Laird, J.P.) in the chair. The hon. secretary read the report, from which it appeared that the number of in-patients treated during 1884 was 286, as against 191 in the previous year. The out-patients numbered 1950, as against 1885 in the previous year. The increase in the number of in-patients had necessitated a considerable increase in expenditure; but as the income in 1884 had been £1271 5s. 3d., against £944 16s. 11d. in the previous year, the treasurer had been able to close the year's account with a deficit of only £54 3s.

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.—The annual meeting of the subscribers to this institution was held on the 20th inst., when it was stated that the number of in-patients for the year had been 655 and of out-patients attended on new tickets 2271. The financial position of the hospital is reported by the committee to be far from satisfactory, the result of the year's working being a loss of £668, the greater part of which may be attributed to the considerable decrease in the amount received from the Lords Commissioners of the Admiralty on the lock wards account. It was decided that the town should be canvassed in order to obtain subscriptions.

PRESENTATIONS.—On the 24th inst. a presentation was made to Dr. T. S. Byass by his friends and patients, among whom he has worked for more than half a century. The testimonial took the form of a large silver salver; of an elegantly designed silver casket of ancient Dutch workmanship, in which was contained 500 guineas; and an illuminated album containing the names of the subscribers.—On Monday evening, Jan. 26th, Mr. E. O. Day, assistant-surgeon to the Royal Hospital for Children and Women, Waterloo-road, was presented with a very handsome writing-desk as a mark of respect from some of his old patients at the South London Medical Aid Institute, from which Society he has just retired.

Medical Appointments.

Appointments for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BENNETT, FRANCIS GRAHAM, M.R.C.S., L.S.A.Lond., has been appointed Assistant Surgeon to the National Hospital for Diseases of the Heart and Paralysis, Soho-square.

BRUCE, GEORGE MALLACK, M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the London Temperance Hospital, Hampstead-road, vice Harold Simmons, resigned.

DAVIS, GEORGE AUGUSTUS, M.A., M.B., B.C.Cantab., M.R.C.S., has been appointed Senior House-Surgeon to the Ardwick and Ancoats Hospital, Manchester, vice C. A. J. Robertson, M.R.C.S., resigned.

BENSON, ROBERT MARSTON, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Plaistow Hospital, Metropolitan Asylum District.

DARKWOOD, EDMUND S., M.R.C.S. & L.S.A.Lond., has been appointed a Medical Officer to the Royal Kent Dispensary.

DENNISS, W. S., M.B., has been elected House-Surgeon to St. Mark's Ophthalmic Hospital, Dublin.

DICKINSON, J. J., B.A., M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the London Hospital.

ELIOT, ERNEST F., L.R.C.P. & L.M.Ed., L.S.A.Lond., has been appointed Medical Officer to the Reformatory School for Boys, Saltley, Birmingham.

HARRIS, ALFRED C. E., M.B., F.R.C.S.Ed., has been appointed Honorary Physician to the Birkenhead Borough Hospital, vice Stevenson.

HARRIS, THOMAS, M.D.Lond., has been appointed Pathological Registrar to the Manchester Royal Infirmary, vice Robert Maguire, M.D.Lond., M.R.C.P., resigned.

HOBSON, L. J., M.D.Lond., B.S., F.R.C.S.Eng., has been appointed Honorary Medical Officer to the Harrogate Bath Hospital, vice A. Ford, F.R.C.S.Ed., resigned.

HUDSON, T. J., M.D., L.R.C.P.Lond., has been appointed Medical Referee to the English and Scottish Law Life Assurance Company and to the National Life Assurance Company, for Leeds and District.

LINDEN, HENRY COOKE, L.F.P.S.Glas., L.R.C.P.Ed., has been appointed Medical Officer for the West District of the Bingham Union.

LING, HAROLD CHARLES, L.R.C.P.Ed., L.F.P.S.Glas., has been appointed Medical Officer to the Workhouse, Scarborough Union, vice De Renzy.

LOWE, ALEXANDER, M.B., C.M.Glas., has been appointed Medical Officer of Health for the Llanelly Division of the Crickhowell Rural Sanitary District, vice Skrimshire, resigned.

MURRAY, WILLIAM G., M.B., C.M.Ed., has been appointed Medical Officer for the Rickmansworth South District of the Watford Union, vice Whiteley.

PHIPPS, JOHN BLAKEMORE, M.D., M.R.C.S., has been appointed Health Officer for the Shire of Romsey, Victoria.

ROBERTSON, R. S., M.R.C.S., L.R.C.P.Ed., has been appointed Junior House-Surgeon to the Ardwick and Ancoats Hospital, Manchester, vice H. Scott, M.B., resigned.

SWANSTON, CHARLES, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Acting Visiting Surgeon to the Mudgee Gaol, New South Wales.

WARTERS, WILLIAM A., L.R.C.P., L.R.C.S., L.M., has been appointed Assistant Medical Officer to the Nottingham Friendly Societies' Medical Institution.

Births, Marriages, and Deaths.

BIRTHS.

BALLARD.—On the 22nd inst., at Walford House, Smarden, the wife of Philip Ballard, L.R.C.P.Lond., M.R.C.S.Eng., of a son.

CRAWFORD.—On the 21st inst., at 5, St. John's-park, Blackheath, the wife of Dr. Crawford, Director-General, Army Medical Department, of a son.

OLIVER.—On the 19th inst., at 3, Eldon-square, Newcastle-upon-Tyne, the wife of Thomas Oliver, M.D., M.R.C.P.Lond., of a daughter.

OWEN.—On the 24th inst., at The Hollies, Shore-road, Hackney, the wife of William Owen, M.R.C.S., of a son.

MARRIAGE.

HUTCHINSON—TEARLE.—On the 22nd inst., at the Parish Church, Gazeley, near Newmarket, by the Rev. J. Hutchinson, Vicar of Kimbolton, Herefordshire, assisted by the Rev. E. Tearle (uncle of the bride), Rector of Stockton, Norfolk, and the Rev. E. H. Littlewood, Vicar of All Saints, Newmarket, Walter Hutchinson, Surgeon, of Newmarket, to Rosa Mary, second daughter of the Rev. F. Tearle, M.A., Rural Dean, Vicar of Gazeley-cum-Kentford, Suffolk.

DEATHS.

BALDING.—On the 24th inst., at Shefford, Beds., from locomotor ataxy, Charles Culledge Balding, M.R.C.S., L.S.A.Lond. (formerly of Her Majesty's Medical Staff in the Crimea), second son of the late James Balding, M.R.C.S., of Barkway, Herts, aged 52.

BROWNE.—On the 22nd inst., suddenly, at his residence, Ridgeway, Southampton, Joseph Hullett Browne, M.D., late of Gordon-square, London, eldest son of Joseph Browne, Esq., of Holcombe House, Gloucestershire, aged 65.

DICK.—On the 22nd inst., at Dalrymple-crescent, Edinburgh, John Dick, M.D., late of Midcalder.

JONES.—On the 21st inst., at 1, Loraine-place, Holloway, N., Dr. Derry Jones, aged 41.

ORFORD.—On the 21st inst., at Bradden Rectory, Towcester, William C. Orford, M.R.C.S., late of Birmingham and Hull, aged 60.

OSBORN.—On the 23rd inst., at Bournemouth, of consumption, William Henry Osborn, M.R.C.S., only son of the late John Osborn, of Newnham-on-Severn, Gloucestershire, aged 30.

SELWOOD.—On the 23rd inst., at Hursley, Winchester, Henry Corpe Selwood, M.D.

WOOLCOTT.—On the 19th inst., at Ramsgate, John Woolcott, F.R.C.S.E., Founder and Consulting Surgeon of the Kent County Ophthalmic Hospital, Maidstone; formerly of Brook-street, Grosvenor-square.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, February 2.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Inaugural Address by the President.—Casual communications by Messrs. Storer Bennett, Walter H. Coffin, and A. S. Underwood.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. T. Lauder Brunton: Digestive Disorders, their Consequences and Treatment (Lettsomian Lecture).

Tuesday, February 3.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., and on Fridays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

TOBACCO POISON.

La Gazzetta degli Ospitali reports that experimental researches on the physiological action of tobacco have led Dr. Zulinsky to the following conclusions: The poisonous action of tobacco smoke does not wholly depend on nicotine; when this is eliminated tobacco smoke still remains noxious, on account of the alkaloid colidine. It also contains oxide of carbon, hydrocyanic acid, and other deleterious principles.

Dr. Gurdon, Mr. Daunt, and others.—We must refer our correspondents to the paper whose title was given in the annotation.

Mr. John Horsfall.—We could scarcely notice the case without the particulars, which are not included in the paragraph sent us.

Mr. Joseph Abbott.—We have no recollection of the communication.

Mr. Gross.—Thanks. Next week.

AN APPARENTLY INSTINCTIVE APPETITE.

To the Editor of THE LANCET.

SIR,—The following case will, I think, be considered of very unusual occurrence. It is that of a child having a voracious and apparently instinctive appetite for mortar.

W. T——, aged three years, is a pale, unhealthy-looking boy, decidedly rickety, with thickened bones at wrist and ankle-joints, carious teeth, and enlarged abdomen; he is also backward in his walking, not having full locomotive powers. His mother informed me that up to two years of age he was a fine baby; he then had an attack of bronchitis, and was treated at a London hospital, where he was offered admission, which his mother refused. The attack left him in a weak state, and soon after that time he showed signs of rickets. About eight months ago he exhibited a great desire for eating mortar. The mother discovered his propensity by observing that the wall near his bed was stripped of paper and holes picked in it. On inquiring into the cause, she found that the boy used to eat the mortar, and his eagerness after it was so great that he would get, even in inclement weather, into the yard and pick the walls, and if prevented he cried. On occasion the child has been deprived of his mortar, and invariably when it is kept from him he vomits his food, and when had recourse to the symptom ceases. So at the present time it is the ordinary routine of his little sisters to collect mortar, which must not contain too much sand as he is particular in the quality. Lime-water has been substituted, but this the child refuses to be contented with, and will have his food in more solid form. He is now suffering from small-pox, and, on waking up in the night, cries for a piece or two of lime before going to sleep again. The quantity consumed during twenty-four hours is rather more than half a teacupful. His mother tells me he has never been weaned, and her custom has been to suckle her other children up to three years of age. To corroborate the mother's statement, I have frequently seen him partake of the mortar, which he crunches up and swallows with great relish.—I am, Sir, yours truly,

Lower Norwood, Jan. 19th, 1885. CHAS. E. ADAMS, M.R.C.S., L.S.A.

SEWER VENTILATION.

Medical Officer of Health.—Our correspondent is quite right. It is wrong to ventilate the sewers into the streets. Ventilating shafts should in all cases be constructed, and carried up, to a level higher than that of the houses, and kept well away from chimneys to avoid down-draughts. Street-level ventilators are simply so many apparatus for the dissemination of sewer-gas. The closed system of sewers or drains should offer no means of escape to the gas below a level higher than the windows of adjacent houses. Our correspondent should insist on the principle he has laid down. It is the only true and safe one. To multiply the low-level openings will be to multiply the points from which sewer-gas is discharged into the district, and to increase the spread of disease.

Dr. James Gairdner.—The work in question is entitled to the trust placed in it by our correspondent. It is based, like all such works, on Percival's treatise; but it takes note of later authorities, and is characterised throughout by good judgment and Christian feeling.

Dr. Lowndes, Mr. J. Goodwin Shea, Mr. Shirley Woolmer, and others.—We think the facts of the case have been sufficiently set forth.

Mr. J. H. Brown.—There does not seem to be any need of exposition of the matter.

CAFFEINE.

To the Editor of THE LANCET.

SIR,—As Mr. Nelson Hardy speaks so favourably of this drug and its heart-tonic action—the heart being probably secondarily impressed through the ganglionic system and vagus—I would fain mention a few instances where I also have found it of great value. In three cases lately treated with small doses of caffeine the improvement, which was well marked, was doubtless due to the stimulating action of this drug.

CASE 1.—A man fell a distance of about 20ft., striking his head severely, and sustaining a few slight contusions and momentary concussion, which were followed by constant pain in the head and down the spine. The usual treatment was found to be ineffective, and the use of bromide and iodide of potassium in small and large doses brought no relief. After nearly two months' observation caffeine was tried, and this soon rendered the heart's action normal, which had previously been increased in frequency and impulse. The headache subsided, and the patient, a navvy, soon returned to his work.

CASE 2.—This patient had received a severe blow on the head from a heavy piece of metal falling from a height. The wound, which was deep and ragged, soon healed, but left the man subject to intense frontal headache, which the bromide and iodide of potassium failed to relieve. By the use of caffeine in three-grain doses marked relief was soon obtained, and, this treatment being persevered with for a few days, complete cure of the giddiness and frontal headache followed.

CASE 3.—This was a case of chronic ovaritis (left) in a female aged twenty-five, married, and mother of one child. The patient had been subject to frontal headache a day or two previous to menstruation (which was regular and natural). Caffeine in three-grain doses three times a day completely removed the neurosis.

The only objection to this drug at present seems to be its costliness.

I am, Sir, yours truly,

EVERARD H. SAUNDERS, M.R.C.S., &c.,
Jan. 24th, 1885. Surgeon R.N.

A NEW EXACTION OF FRIENDLY SOCIETIES' MEDICAL ASSOCIATIONS.

Lex would feel obliged if the Editor of THE LANCET, or any of his readers, could inform him whether an engagement entered into between a friendly societies' medical association and their surgeon, binding the latter not to practise in the neighbourhood for two years after ceasing to hold the appointment, can be sustained in law, and whether such a case has actually been decided. Local solicitors do not seem clear about the question. [Perhaps some of our readers may be able to answer this question, which, however, we fancy, has not come before the courts.—ED. L.]

E. D. (Desford).—The symptoms given are insufficient to form a diagnosis upon. The eyes should be carefully examined, and especially for errors of refraction and alteration of tension in the globe.

Lewis.—The case doubtless is one of "pneumatocele," or "hernia of the lung."

PRURITUS VULVÆ.

To the Editor of THE LANCET.

SIR,—In answer to "M.D.'s" inquiry, he will find that "pixene," used as I ordered for lotions—viz., two drachms of pixene and half an ounce of glycerine to six ounces of water—will have at once a soothing and curative effect.

I am, Sir, yours obediently,
Princess Risborough, Jan. 26th, 1885. GEO. LOCKE, L.R.C.P.Ed.

To the Editor of THE LANCET.

SIR,—"M.D." seeks, at page 188 of your last issue, information regarding the best remedy for pruritus vulvæ. Among the numerous remedies to be found at Section 46 of the Medical Digest few equal in efficacy a saturated solution of boracic acid.

I am, Sir, yours obediently,
RICHARD NEALE, M.D.Lond.
South Hampstead, N.W., Jan. 26th, 1885.

THE FORFAR DISEASED MEAT PROSECUTION.

REFERRING to Dr. Murray's communication on this subject, Mr. Andrew Spreull, F.R.C.V.S., as one of the local veterinary surgeons referred to sends us a letter which, owing to its length, we are unable to publish in full. Mr. Spreull states that, instead of agreeing entirely with Dr. Murray in considering the case one of tuberculosis, he regarded it as something akin to, or, as he put it in his evidence, "of the nature of," tubercular disease, having at the same time considerable doubt if that was really its genuine character. The result of microscopical examinations of certain portions of the diseased product tend, Mr. Spreull states, to confirm him in his opinion that tubercle did not exist. Doubt is cast upon Dr. Murray's statement that extensive deposits existed in the lungs, the writer of the present communication averring that disease existed only in the liver.

M.D. would do well to refer to a letter on the subject which appeared in THE LANCET of March 25th, 1882, p. 508.

INDIAN ACONITE AND HYDROCHLORATE OF COCAINE IN THE TREATMENT OF CHILBLAIN.

To the Editor of THE LANCET.

SIR,—The sudden return of frost induces me to lay before your readers a brief account of the effects of the above-named drugs in some cases of chilblain that recently came under my notice; first, because the action of the one, in my experience, is superior to all other remedies in this affection, and, secondly, because the other is a new remedy of which much has been written of late.

In one case, after a fair trial of many remedies without any permanent benefit, from a favourable recollection of its good effect as a topical application in gout, I was induced to try the aconite. The preparation I used first was the tincture of the B.P., which I soon laid aside for that of the A. ferox, containing one part of the root to ten of proof spirit, as described by me in the remarks on this drug which I had the honour to make before the last meeting of the British Medical Association. This tincture is prepared by Mr. Martindale. It was well painted over the toes and inflamed portion of the feet for a quarter of an hour on four different occasions in the course of an evening, with the result of not only relieving all painful sensations, but of reducing the inflammation to such a degree that on the following day the patient was enabled to wear a boot for the first time during five days. Lotions may also be used. In a second trial it was equally useful, though, owing to an early application, the case was of a milder character. In another I first tried the hydrochlorate of cocaine, in the proportion of one grain to a drachm of vaseline; and I found that although this agent speedily relieved the tingling sensation, it had no antiphlogistic effect, and is therefore, *per se*, utterly incompetent in the disease under consideration. When supplemented by the aconite, as in the other cases, the cure was rapid and satisfactory. As a combination of these remedies might prove useful, I would suggest that those who have an opportunity should try it, never forgetting the danger of aconite wherever a breach of cutaneous continuity exists, which breach, though impending, a judicious application is likely to prevent, as it did in the first case under consideration. I will not take up your space with any remarks explanatory of the *modus operandi* of the aconite tincture, simply contenting myself with an expression of opinion that they would be in such direction as would lead to the use of this agent as a topical application in frost-bite. The Indian plant, probably owing to its more exuberant growth, I consider the more effectual.—I am, Sir, your obedient servant,

D. H. CULLIMORE, M.D., M.R.C.P., &c.
Welbeck-street, W., Jan. 26th, 1885.

Enquirer.—There should have been an article in the agreement to prohibit the course referred to. It is hardly a question of etiquette, so far as our correspondent is concerned.

TREATMENT OF FUNCTIONAL AMENORRHŒA.

To the Editor of THE LANCET.

SIR,—Kindly allow me through the medium of your columns to endorse the words of Dr. Pollock respecting the treatment of "functional amenorrhœa" by bogbean (*Menyanthes trifoliata*). I have used it for the last eighteen months, and am pleased to say I have always been satisfied with its results. I was first cognisant of its value in a case that would not yield to the usual remedies, when I was induced to prescribe it by my father, who, I may say, has used it for the last thirty-five years with success.

Allow me to thank Dr. Pollock for placing it before the profession, as I think it one of those simple remedies so often neglected.

I am, Sir, yours faithfully,
Burley, Leeds, Jan. 20th, 1885. ERNEST WHITE.

Dr. Jas. Niven.—We cannot comply with our correspondent's request.

M.B.Edin.—The controversy is closed.

A FACT FOR CIGAR-SMOKERS.

To the Editor of THE LANCET.

SIR,—The following fact is, I think, worthy of record in THE LANCET. During a recent tour in the United States, I visited one of the great centres of tobacco industry, and there I saw a white workman freely using his saliva in fashioning the pointed ends of cigars.

I am, Sir, your obedient servant,
London, Jan. 18th, 1885. M.D.

H. W., Surgeon.—Examination should be made carefully for phimosis, stricture, gleet, or any very sensitive patch in the urethra, and, if either be found, curative treatment adopted. The passage of a full-sized metal bougie every day or so is particularly useful. A hot bath every night may relieve. Sexual excitement of all kinds should be prohibited; and no aphrodisiacs, such as strychnia, should be given. These measures, with attention to the bowels, may be expected to result in recovery.

M.R.C.S.—We can only refer our correspondent to our advertising columns.

A WARNING.

To the Editor of THE LANCET.

SIR,—You would confer a great favour on me by inserting this letter in the next number of your valuable journal, as it might prevent others falling victims.

By this afternoon's post I received a letter from a brother officer in Scotland, saying he had received a letter signed with my name asking for the loan of £6 or £7 for a few days, and giving an address at Catford, S.E. The cheque was forwarded, as requested, but the letter was returned through the Dead Letter Office; the cheque, however, had been abstracted, and subsequently cashed. As many others may have received similar applications, I would wish it to be be known that I have not written to anyone for loans, nor do I know anything of the matter beyond what I have stated. This is the second time that this trick has been practised on medical officers in this district within the last month or so. I am, Sir, yours faithfully,

GEO. T. TREWMAN, M.B.,
Surgeon, Medical Staff.

Gosport, Jan. 28th, 1885.

ERRATA.—In Prof. Buchanan's paper published last week, p. 148, first column, line 38, for "over" read *out;* second column, line 33, for "anterior circumflex" read *posterior* circumflex.—In the report of Mr. Page's case of wound of the cornea, p. 155, on the last line of the first column, the figure 3 should be 2; and on line 22, in the second column, the figure 2 should be 3.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Clinical Lectures ON SCLERODERMA.

By H. RADCLIFFE CROCKER, M.D., M.R.C.P.,
PHYSICIAN TO THE SKIN DEPARTMENT OF UNIVERSITY COLLEGE HOSPITAL, PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

LECTURE I.

DIFFUSE SYMMETRICAL SCLERODERMA.

(Concluded from p. 193.)

BEFORE I comment on the case already described, I will relate the history of the other, and show how she has altered since she first came under our notice.
